Infectious Diseases: The Role of the Healthcare Professional

10

Felicity Nicholson

Learning Objectives

Explanation of the importance of taking standard precautions with all patients.

Treatment of an 'at risk exposure' and organization of a management plan.

Demonstrate the ability to provide advice to the police with regard to the effective management of the common infectious diseases seen in custody.

Introduction

Infections have plagued healthcare professionals (HCPs) for centuries, both in the diagnosis of the specific diseases, and the identification and subsequent management of the causative agents. There is a constant need for information as new organisms emerge, existing ones develop resistance to current drugs or vaccines, and there are changes in epidemiology and prevalence. In the twenty-first century, obtaining this information has never been more important. Population migration, and the relatively low cost of flying, means that unfamiliar infectious diseases may be brought into industrialized countries. An example of this was an outbreak of severe acute respiratory syndrome (SARS), which was first recognized in 2003. Despite modern technology and a huge input of money, it took months for the agent to be identified, a diagnostic test to be produced, and a strategy for disease reporting and isolation to be established.

A further example of how population migration can result in the spreading of disease was with the appearance of swine influenza A (H1N1). In March 2009, the first case was reported in Mexico; by June 2009, over 22,000 cases had been reported in 70 countries, thus fulfilling the criteria for a pandemic. Challenges ensued with decisions about treatment and then the distribution and administration of specific vaccine. More recent examples include the discovery of Corona virus Mers CoV

which emerged predominantly from the Middle East in 2012 and spread to many countries. In 2014 there was an Ebola outbreak in West Africa which lead to cases being transferred to Europe and the USA.

There is no doubt that other new and fascinating diseases will continue to emerge. For the healthcare professional dealing with infections presents two main problems. First, managing detainees or police personnel who have contracted a disease and may be infectious or unwell, and second, handling complainants of assault, including police officers, who have potentially been exposed to an infectious disease. The latter can be distressing for those involved, compounded in part from an inconsistency of management guidelines, if indeed they exist.

With the advent of human rights legislation, increasing pressure is being placed on HCPs with regard to consent and confidentiality of the detainee. Therefore, it is prudent to pre-empt such situations before the consultation begins by obtaining either written or verbal consent from the detainee to allow certain pieces of information to be disclosed. If he/she does not agree, then the HCP must decide whether withholding relevant details will endanger the lives or health of those working within custody or others with whom they may have had close contact (whether or not deliberate). Issues of consent and confidentiality are discussed in detail in Chap. 2.

Adopting standard precautions with all detainees will decrease the risk to staff of acquiring such diseases and will help to stop unnecessary overreaction and unjustified disclosure of sensitive information. For victims of violent or sexual assault, a more open-minded approach is needed (see also Chap. 3). If the assailant/suspect is known, then it may be possible to make an informed assessment of the risk of certain diseases by ascertaining their lifestyle and where possible by asking permission to test for certain diseases. If, however, the assailant is unknown, then this is not possible and so it is best to assume they are infected. This chapter aims to highlight the most common infections encountered by the healthcare professional. It aims to dispel "urban myths" and provide a sensible approach for achieving effective management.

Standard Precautions

The risk of exposure to infections, in particular to blood-borne viruses (BBVs), can be minimized by adopting measures that are considered good practice in the UK, the USA and Australia [1–3]. The Guidance for Clinical Health Care Workers: Protection against infection with blood borne viruses, (DOH 1998) contains standard precautions. The aim of adopting standard precautions is to prevent transmission of BBVs by considering that blood and other body fluids are potentially infectious. It means never assuming that there is no risk. If every patient is assumed to be potentially infected with a blood borne infection the same precautions to prevent exposure should be used for every procedure.

Healthcare professionals should wash their hands before and after contact with each detainee or victim. A laminated copy of good hand washing techniques (e.g. from the National Patient Safety Agency) should be displayed by the sink in the

WIT.0043.0086.0346

medical room. Liquid soap from a wall mounted dispenser should be used routinely. Alcohol hand rub can be used as an alternative if hands are dry and physically clean. It should not be used if the patient has had diarrhea in the last 48 h as it is not effective against Norovirus or Clostridium difficile. Police officers should be encouraged to wash their hands after exposure to body fluids or excreta. All staff should wear gloves when exposure to body fluids, mucous membranes or non-intact skin is likely. Gloves should also be worn when cleaning up body fluids or handling clinical waste including contaminated laundry. Only single-use gloves which are powder free should be used and must conform to the requirements of British and EN standards and be CE marked or equivalent [1–3]. A synthetic alternative conforming to the same standards should also be available for those allergic to latex e.g. nitrile.

All staff should cover any fresh wounds (less than 24 h old), open skin lesions or breaks in exposed skin with a waterproof dressing. Single gloves have been shown to remove 86% of surface blood and therefore reduces the risk of acquiring a BBV infection. Doubling gloving removes even more. Gloves should be worn when taking blood, providing this does not reduce manual dexterity and therefore increase the risk of accidental percutaneous injury.

A designated person should be allocated to ensure the clinical room is kept clean and sharps containers and clinical waste bags should be removed on a regular basis. Clinical waste must be disposed of in "hazard bags" and should never be over-filled. After use they should be double-bagged and sealed with "hazard tape". The bags should be placed in a locked designated waste disposal store and removed by a professional company. When cells are contaminated with body fluids, a professional cleaning company should be called to attend as soon as possible. Until such time, the cell should be deemed "out of action".

Ideally there should be a designated infection control lead who has the overall responsibility of auditing the premises and ensuring that they meet infection control standards.

Sharps Awareness

The main risk of sharps injury is the potential acquisition of the major blood borne viruses (BBV) hepatitis B, hepatitis C, and HIV. Other infectious agents can also be transmitted through sharp injuries including but not limited to Human T Lymphotrophic retroviruses (HTLVI & II), Cytomegalovirus, and Epstein Barr virus.

Whether or not an infection is acquired depends on a number of factors including the person's immune system, the type of sharp involved, the depth and site of the sharp injury and how infectious the blood was at the time of the injury.

Whilst the number of sharp injuries leading to infection is small, there are the direct costs of the medication to consider alongside the psychological impact which is harder to quantify. There may also be side effects from the medication and time lost from work.

There is a legal requirement in the UK under the Environmental Protection Act (1990) and the Control of Substances Hazardous to Health Regulations 2002 (COSHH) to dispose of sharps in an approved container. In the USA, the Division of Healthcare Quality Promotion (DHQP) on the Centers for Disease Control and Prevention (CDC) website provides similar guidance. Further guidance can also be find in the 'Stop Sticks' campaign run by the National Institute for Occupational Safety and Health (NIOSH).

In custody where sharps containers are transported off site, they must be of an approved type and the correct UN approved color. In the UK, such a requirement is contained within the Carriage of Dangerous Goods (Classification, Packaging and Labelling) and Use of Transportable Pressure Receptacles Regulations 2009. These measures help to minimize the risk of accidental injury. Further precautions include wearing gloves when handling sharps and never bending, breaking or re-sheathing needles before disposal. Sharps bins should never be more than three quarters full, they should be secured to the wall when in use and should be placed at a safe height for those using it to minimize the risk of inoculation injuries when disposing of the sharps.

Contaminated Bedding

Any bedding that is visibly stained with body fluids should be handled with gloves. There are only three acceptable ways of dealing with contaminated bedding:

1. Laundering with a detergent at a minimum temperature of 71 °C (160 °F) or at a lower temperature (22–50 °C) with water containing detergent and 50–150 ppm of chlorine bleach.
2. Dry cleaning at elevated temperatures/dry cleaning cold followed by steam pressing.
3. Incineration.

It is not considered acceptable practice to share bedding between detainees.

Other Measures

It is not necessary for staff to wear masks or protective eyewear in the custodial setting as the risk of infection is low. However, single use eyewash should be available in the clinical room or contained in other first aid kits located within the police station in case of accidental exposure. Contact lenses should be removed prior to eye washing.

Formulation of Guidelines

An example of good practice is contained within the UK Health Department's 1998 document [1] which states "that it is the responsibility of Health Authorities, Health Boards and NHS Trusts to create their own local guidelines to prevent the spread of

WIT.0043.0086.0348

BBVs in the health care setting". The Health and Social Care Act 2008 Code of Practice on the prevention and control of infections and related guidance also sets out the standards for the NHS and other regulated health care providers. Such guidelines may not exist in other work places. If this is the case, then they should be formulated as soon as possible. It is also prudent to pre-arrange a system of referral with the nearest hospital that has an Emergency Department, a Genito-Urinary Department and access to a Specialist. The latter may be a consultant in Virology, Microbiology, Infectious Diseases or Genito-Urinary Medicine. Similar guidance in the USA can be found in "The Guideline for Infection Control in Health Care Personnel" [4].

Most exposures to staff usually result from a failure to follow accepted practice; however, accidents can happen no matter how much care is taken. All healthcare professionals working in custody should understand what constitutes a risk and should have had relevant infection control training. This involves taking a detailed history of the incident, including the type of exposure, the body fluids involved and when it occurred.

This information could help to allay unnecessary anxiety from the outset and will ensure that the recipient of the exposure is referred, if appropriate, to the designated hospital at the earliest opportunity. Knowledge of precise treatment protocols is not required, but it is helpful to be able to explain to the recipient what to expect. For example, he or she will be asked to provide a voluntary baseline blood sample for storage and a number of follow-up samples for testing depending on the nature of the exposure. This is especially relevant for hepatitis B (HBV), hepatitis C (HCV) and human immunodeficiency virus (HIV). Most usually, this will be complete by 12 weeks, but on occasion testing may be extended to 6 months after the incident.

Sexual assault complainants should ideally be referred to specialist centers, if available. A police station should only be used as a last resort because the environment is often hostile and there is no ready access to the necessary treatment and ongoing management (see Chap. 3).

Routes of Transmission

Organisms may utilize more than one route. For ease of understanding, the infections discussed in this chapter are classified according to their primary route, i.e. transmission through blood and body fluids; through contact with lesions or organisms; through the respiratory route; and through the fecal-oral route.

Transmission Through Blood and Body Fluids

The BBVs which present most cross-infection hazard to staff or victims are those associated with persistent viral replication and viremia. These include hepatitis B (HBV), hepatitis C (HCV), hepatitis D (HDV), and human immunodeficiency virus (HIV).

WIT.0043.0086.0349

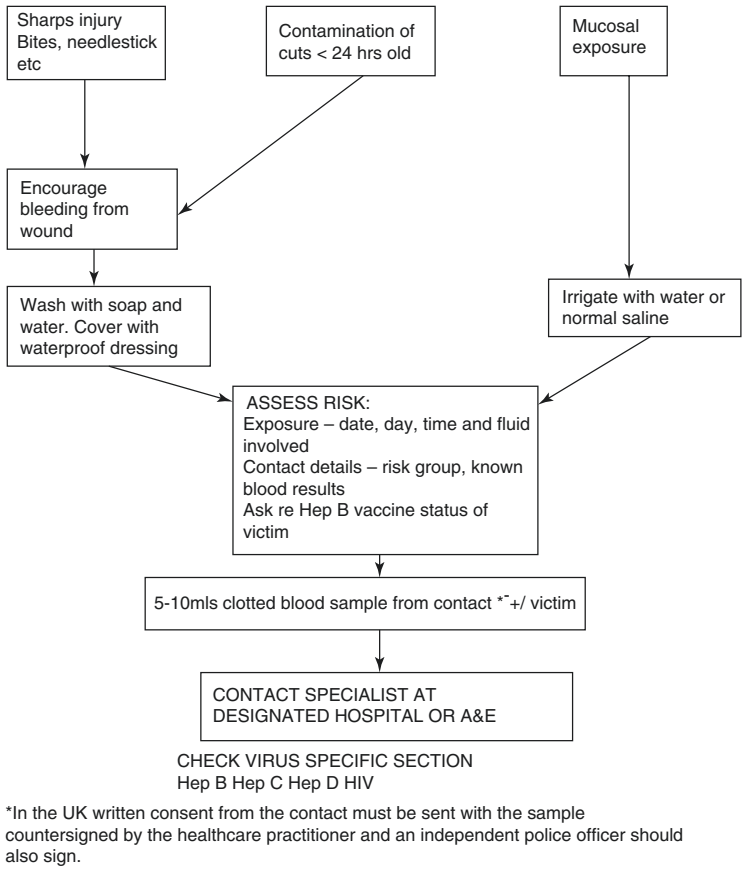

Fig. 10.1 Immediate management following occupational exposure to blood-borne viruses (BBVs)

In general, risks of transmission of BBVs arise from the possible exposure to blood or other body fluids. The degree of risk varies with the virus concerned and will be discussed under the relevant sections. Figure 10.1 illustrates the immediate management following a percutaneous injury, mucocutaneous exposure, or exposure through contamination of fresh cuts or breaks in the skin.

Hepatitis B

Epidemiology and Prevalence

HBV is endemic throughout the world with populations showing a varying degree of prevalence. Approximately 2000 million people have been infected with HBV. In

WIT.0043.0086.0350

Table 10.1 Prevalence of chronic hepatitis B by world areas

Prevalence	Areas
Low <2%	Most of western Europe including the UK, North America, Australia (excluding the Aborigines), New Zealand
Intermediate (2–8%)	Mediterranean, the Amazon Basin, most of the Middle East, japan, the Indian Sub Continent and southern parts of Eastern and Central Europe
High >8%	Sub Saharan Africa, most of Asia and the Pacific Islands

2015 there were 257 million people living with chronic infection world-wide [5]; and world-wide in that same year HBV killed 887,000 people.

With the development of a safe and effective vaccine in 1982, the World Health Organization (WHO) recommended that HBV vaccine should be incorporated into national immunization programmes by 1995 in those countries with a chronic infection rate of 8% or higher and into all countries by 1997. In 2015 global coverage with the three doses of hepatitis B vaccine in infancy reached 84%. However coverage with the first birth dose of vaccine remains low at 39%. Meaning that some of the poorer countries were not meeting their targets [5].

In the United Kingdom, the overall prevalence of chronic HBV is around 0.1–0.5% [6] which according to the WHO classification based on the prevalence of HBsAg is low (less than 2%). Other low prevalence areas include most of Western Europe and North America. High prevalence which is found in sub Saharan Africa, most of Asia and the Pacific Islands has a prevalence of more than 8% (see Table 10.1).

Symptoms and Complications

The incubation period is approximately 40–160 days. As the name suggests, the virus primarily affects the liver. Many people with acute infection have a sub clinical or flu-like illness. Typical symptoms include malaise, anorexia, nausea, mild fever, and abdominal discomfort and may last from 2 days to 3 weeks before the insidious onset of jaundice. Joint pain and skin rashes may also occur due to immune complex formation. Infections in the newborn are usually asymptomatic.

The majority of patients with acute HBV make a full recovery and develop immunity. Following acute infection, about 1 in 300 patients develop liver failure, which may result in death.

Chronic infection develops in around 90% of neonates, about 20–50% of children infected between the ages of 1–5 years old and around 5% of adults. Neonates and children are usually asymptomatic. Adults may have only mild symptoms or may also be asymptomatic. Approximately 20–25% of chronically infected individuals (depending on age of acquisition) will develop cirrhosis over a number of years. This may also result in liver failure or other serious complications including hepatocellular carcinoma, though the latter is rare. The overall mortality rate of HBV is estimated at less than 5%.

WIT.0043.0086.0351

Table 10.2 Significance of markers

Name	Infectivity	Immunity	Risk following needle stick (%)
HBsAg	Yes	No	Only marker = 10–20
HBeAg	Yes	No	With HBsAg = 30–40
HBeA	Yes	Yes	With HBsAg ≤ 10
HBCA	No	Yes	0
HBSA	No	Yes	0

HBsAg Hepatitis B surface antigen, *HbeAg* hepatitis B e antigen, *HBeA* hepatitis B e antibody, *HBCA* hepatitis B core antibody, *HBSA* hepatitis B surface antibody

Period of Infectivity

A person is deemed infectious if hepatitis B surface antigen (HBsAg) is detected in the blood. In the acute phase of the illness, this can be for as long as 6 months. By definition, if HBsAg persists for after this time then the person is deemed a carrier. Carriers are usually infectious for life. The degree of infectivity depends on the stage of disease and the markers present in Table 10.2.

Routes of Transmission

The major routes include: parenteral (e.g. needlestick injuries, bites (rare), blood transfusions (rare in the UK as blood donors and donations are screened), tattooing, acupuncture and dental procedures, where equipment is inadequately sterilised); mucous membrane exposure (including mouth, eyes and genital mucous membranes including vaginal and anal intercourse), through perinatal transmission from mother to child and contamination of broken skin (especially when <24 h old).

At-Risk Groups

HBV is an occupational hazard for anyone who may come into contact with blood or bloodstained body fluids through the routes described above. Saliva alone may transmit HBV. The saliva of some people infected with HBV has been shown to contain HBV-DNA concentrations 1/1000–1/10,000 of that found in their serum [7]. This is especially relevant for penetrating bite wounds. Infection following exposure to other body fluids, e.g. bile, urine, feces and CSF, has never been demonstrated unless the fluids are contaminated with blood.

In 2016 in England there were 453 reported cases of acute or probable acute cases of hepatitis B [8]. The prevalence of acute hepatitis B in London was 1.7/100,000 population compared with 0.82/100,000 nationally. Where a route of transmission was identified, in 64.6% cases the mode of transmission was through heterosexual exposure. Men who have sex with men accounted for 14% of the cases. However, only 36% had information about the associated exposure. None the less the data presented suggests that the number of cases of acute hepatitis B in PWID has remained low in 2016. Periodic surveys in PWID show that the hepatitis B

WIT.0043.0086.0352

prevalence is around 1 in 500 [9] This is thought to be in part due to increased awareness, and self-reported hepatitis B vaccine uptake. In 2016 about 75% of PWID reported having hepatitis B vaccine, but this level is no longer increasing. Uptake is especially low in younger age groups and amongst new injectors [8].

Evidence has shown that the virus may also be spread among members of a family through close household contact. This is thought to be through kissing, sharing toothbrushes, razors, bath towels, etc. [10–12]. This route of transmission probably applies to institutionalized patients.

In the Public Health England Health and Justice Annual Review 2017/2018 [13] the prevalence of blood-borne viruses was four times higher in the prison population than in the general population. Hepatitis B prevalence was reported as 0.6% in the prison population versus 0.16% in the general population.

HBV can be transmitted vertically from mother to baby during the perinatal period. Around 80% of babies born to mothers who have either acute or chronic HBV become infected and most will develop chronic HBV. This has been limited by the administration of HBV vaccine to the neonate. In industrialized countries all antenatal mothers are screened for HBV. Vaccine is given to the neonate ideally within the first 12 h of birth and at least two further doses are given at designated intervals. The WHO recommends this as a matter of course for all women in countries where prevalence is high. However, the practicalities of administering vaccine that has to be stored at the correct temperature and limited access to medical care mean that there is a significant failure of vaccine uptake and response.

Disease Prevention

In industrialized countries, HBV vaccination is recommended for those deemed at risk of acquiring the disease

1. Through occupational exposure
2. Homosexual/bisexual men
3. People who inject drugs
4. Female commercial sex workers
5. Patients with chronic renal or hepatitis disease
6. Sexual partners of people with acute or chronic HBV including victims of sexual assault
7. Family members of people with acute or chronic HBV
8. Newborn babies whose mothers are infected with HBV. If the mother is HBeAg positive, then HBV-specific immunoglobulin (HBSIG) should be given at the same time as the first dose of vaccine
9. If the baby is born to an HBV negative mother but is going home to another HBV positive household member they should receive one dose of Hepatitis B vaccine before leaving hospital and then continue on the routine schedule [10]
10. Institutionalized patients and inmates of custodial institutions.
11. As of October 2017, hepatitis B has been incorporated in a hexavalent vaccine which is given to all babies born in the UK with doses being at given at 2, 3 and 4 months

WIT.0043.0086.0353

Ideally, HBV vaccine should be administered prior to exposure. For most adult and child risk groups an accelerated schedule is used. Three doses of vaccine are given at 0, 1 and 2 months because it has been shown that there are higher completion rates particularly amongst those who are less compliant (e.g. PWID). The improved compliance will probably offset against the slightly reduced immunogenicity of this accelerated schedule compared with the 0, 1 and 6 month schedule. Giving a booster after a year where possible will provide a similar immune response.

If the individual is considered to be at more immediate risk then a super accelerated course can be used with three doses given on day 0, 7 and 21. A fourth dose would be given 12 months after the first dose to ensure long term protection. This schedule is licensed in adults over 18 and is particularly useful for people travelling to areas of high endemicity, prisoners and PWID. It can also be used off license for those aged 16–18 where it is important to provide rapid protection and achieve maximum compliance.

It is believed that in immunocompetent individuals following a successful vaccination course that immunity against hepatitis B lasts for around 30 years. The WHO in 2017 stated that there was no need for a booster dose of hepatitis B vaccine in routine immunization programmes.

For health care workers the 0, 1, 6 month schedule is preferred unless they are going to be engaging in exposure prone procedures in which case a more rapid schedule can be used. A blood test should be done 8–12 weeks after the third dose of vaccine. If the titre is >10 miU/mL then an adequate response has been achieved. In the UK a further dose of vaccine is given at 5 years. In the USA, if an initial adequate response has been achieved, then no further doses of vaccine are considered necessary for Health care workers.

Patients with chronic renal failure or who are on hemodialysis may have poor immunological memory and require further boosts if titres fall below 10 miU/mL.

Post Exposure Prophylaxis

Hepatitis B vaccine administration after exposure varies according to the timing of the incident, the degree of risk involved, and whether the individual has already been partly or fully vaccinated as can be seen in Table 10.3 below.

Hepatitis B specific Immunoglobulin (HSIG) may be used either alone or in conjunction with vaccine. The exact dose given is age-dependent, but must be administered by deep intra-muscular injection in a different site from the vaccine. In an adult, this is usually into the gluteus muscle. If HBIG is being given together with hepatitis B vaccine then it should be given at the same time, ideally within 24 h of an exposure, but can be considered up to 7 days after. It is also used for neonates born to mothers who are HBeAg-positive where the risk of vertical transmission is greatest.

Between 5% and 10% of adults fail to respond to the routine schedule of vaccine. A further full course of vaccine should be tried before deeming them “non-responders”. It is worth considering using Twinrix as there is evidence that the combination of

WIT.0043.0086.0354

Table 10.3 Hepatitis B prophylaxis following exposure—adapted from the Green book Chap. 18 [14]

	Significant exposure		
HBV status of person exposed	Source HBsAg positive	Unknown source	Source HBsAg – ve
Unvaccinated	Accelerated course of Hep B vaccine plus HBSIG with first dose	Accelerated course of Hep B vaccine	Consider course of hepatitis B vaccine especially if at continued risk
Partially vaccinated	One dose of vaccine sat and then finish the course	One dose of vaccine stat and then finish the course	Consider completing the course
Fully vaccinated with primary course	Booster dose of hep B vaccine if last dose ≥1 year ago	Consider booster dose of hep B vaccine if last dose ≥1 year ago	No HBV prophylaxis. Reassure
Known non responder Anti HBS <10 iu 1–2 months after vaccination	HBIG Booster dose of hepatitis B vaccine Repeat HBIG at 1 month	HBIG Consider booster dose of hepatitis B vaccine Repeat HBIG at 1 month	No HBIG Consider booster dose of hepatitis B vaccine

hepatitis A and B vaccines is more immunogenic. Using higher strength (40 μg) hepatitis B vaccine as used in renal patients may also be worth trying in non-responders working in high risk settings. Non responders involved in a high-risk exposure should be given two doses of HBIG administered a month apart and a booster dose of hepatitis B vaccine would also be given. Ideally, the first dose of HBIG should be given within 48 h after exposure and no longer than 2 weeks after exposure.

Management in Custody

For staff or victims in contact with disease, it is wise to have a protocol in place for immediate management and risk evaluation. An example is shown in Fig. 10.1. While healthcare professionals are not expected to administer treatment, it is often helpful to inform persons concerned what to expect (Table 10.2).

Other measures to avoid an exposure include minimizing the risk of exposure by adopting the safe working practices outlined in the "Standard Precautions" section. There should be a protocol in place which explains how the person exposed should be managed and where they need to go to be assessed and treated where necessary. Any potential exposures should be dealt with as soon as possible. Detainees with disease can usually be managed in custody. If the detainee is bleeding, then the cell should be deemed out of action after they have left until it can be professionally cleaned. Contaminated bedding should be dealt with as described previously. If the detainee has chronic HBV and is on an antiviral agent (e.g. tenofovir), then the treatment course should be continued, if possible.

People who inject drugs should be encouraged to be vaccinated and to avoid sharing needles or any other drug paraphernalia (see "Management in Custody" in section "Other Bacteria Associated with Abscess Formation in People who Inject Drugs").

WIT.0043.0086.0355

Hepatitis C

Epidemiology and Prevalence

Hepatitis C virus (HCV) is endemic in most parts of the world. In 2015 it was estimated that 71 million people are living with chronic hepatitis C infection. In that same year there were 1.75 million new infections world-wide [15]. As part of the WHO Global Health Sector Strategy the aim is to eliminate all viral hepatitis by 2030.

Seroprevalence studies carried out among blood donors have shown that the highest prevalence exists in Egypt—13% in 2016. This has been ascribed to contaminated needles used in the treatment of schistosomiasis carried out between the 1950s and the 1980s [16].

Intermediate prevalence (1–5%) exists in Eastern Europe, the Mediterranean, the Middle East, the Indian Sub-continent and parts of Africa and Asia. In Western Europe, most of Central America, Australia and limited regions in Africa including South Africa, the prevalence is low (0.2–0.5%). Previously, America was included in the low prevalence group, but a report published in 2015 [17] indicated that up to 5.2 million Americans, i.e. 1.6% of the population, have antibody to HCV, representing either ongoing or previous infection. It also states that HCV accounts for approximately 15% of acute viral hepatitis in America.

Between 0.5–1% of the UK population are chronically infected with hepatitis C meaning that in 2018 there are 160,000 people living with chronic infection. However, within any country, there are certain groups that have a higher chance of carrying HCV. In the UK the most important risk factor of hepatitis C is injecting drug use accounting for 90% of all lab reports where a risk factor was disclosed [18]. In 2016 54% of people who had injected psychoactive drugs and participated in the Unlinked Anonymous Monitoring Survey (UAMS) tested positive for antibodies to hepatitis C. However, only 52% of those surveyed were aware of their status impacting on the number of people who could seek treatment. The survey also revealed that 18% of participants still share needles but this is still a fall when compared with the 23% recorded in 2005.

There has been a 3% fall in the number of deaths from HCV end stage liver disease and hepatocellular carcinoma between 2014 and 2016. This has been attributed to more patients seeking treatment and an improvement in the treatment.

Symptoms and Complications

After an incubation period of 6–8 weeks, the acute phase of the disease lasts approximately 2–3 years. Unlike hepatitis A (HAV) or HBV, the patient is usually asymptomatic; therefore, the disease is often missed unless the individual has reported a specific exposure and is being monitored. Other cases are found by chance, when raised liver enzymes are found on a routine blood test.

A “silent phase” follows the acute phase when the virus lies dormant and the liver enzymes are usually normal. This period lasts approximately 10–15 years.

WIT.0043.0086.0356

Reactivation may then occur. Subsequent viral replication damages the hepatocytes, and liver enzymes rise to moderate or high levels.

Antibodies develop 4–6 weeks after the acquisition of the virus, with 97% having detectable antibodies by 6 months. RNA can be detected by PCR 2–3 weeks after acquisition of the virus.

Eighty percent of individuals who are HCV antibody-positive are infectious, regardless of the levels of their liver enzymes. Approximately 80% of people develop chronic infection, one fifth of whom progress to cirrhosis. There is a much stronger association with hepatocellular carcinoma than with HBV. An estimated 1.25–2.5% of patients with HCV-related cirrhosis develop liver cancer [19]. Less than 2% of chronic cases resolve spontaneously.

Routes of Transmission

The main route of acquisition for hepatitis C is through injecting drug use, unsafe injection practice, and unscreened blood transfusions. Transmission through the sexual route is not common and only appears to be significant if there is repeated exposure with one or more people infected with HCV [18]. Mother-to-baby transmission is not common, but has been reported [20]. Theoretically, household spread is also possible through sharing contaminated toothbrushes or razors.

Since the disease is often silent, there is a need to raise awareness among the general population on how to avoid infection and to encourage high-risk groups to be tested. Healthcare professionals should also be educated to avoid occupationally acquired infection. An example of good practice is contained within the document 'Hepatitis C strategy for England', issued by the Department of Health in 2002 [19].

Risks from Exposure from HCV RNA-Positive Person

Blood or bloodstained body fluids need to be involved for a risk to occur. Saliva alone is not deemed to be a risk. The risk from a single needlestick incident is 1.8% (range 0–7%). Contact through a contaminated cut is estimated at 1%. For penetrating bite injuries, it is only considered a risk if blood is involved. Blood or bloodstained body fluids have to be involved in transmission through mucous membrane exposure. This may account for the lower than expected prevalence among the gay population.

Management in Custody

Staff/Victims in Contact with Disease

Follow the immediate management flow chart, making sure all available information is obtained. Inform the designated hospital and/or specialist as soon as possible. If the contact is known and is thought to be immunocompromised, and he or she has

WIT.0043.0086.0357

consented to provide a blood sample, it is important to tell the specialist, as their antibody tests may be spuriously negative. In this instance, a different test should be used (polymerase chain reaction [PCR] which detects viral RNA).

The staff member/victim will be asked to provide a baseline sample of blood ideally within 48 h of the exposure. Further samples may be taken at 4–6 weeks and again at 12 weeks. If tests are negative at 12 weeks, but the risk was deemed high, then follow-up may continue for up to 24 weeks. If any of the follow-up samples are positive, then the original baseline sample will be tested to ascertain whether the infection was acquired through the particular exposure.

Treatment of hepatitis C infection has been improved more recently with the use of Direct Acting Antiviral agents e.g. sofosbuvir. These drugs act by targeting non-structural proteins of the virus which disrupts viral replication and infection. They can be given orally, for shorter durations and have an improved safety profile over the pegylated interferons used previously and can cure the infection within 2–3 months. Treatment is usually not started till after 6 months as between 15–45% of people can spontaneously clear the virus in the acute phase. Prior to these drugs being developed Genotype 1 was notoriously difficult to treat. Now with a combination of drugs there is a cure rate of over 90%. Recovery from hepatitis C does not confer immunity and it is possible to become infected again [21].

Co-infection with HIV also occurs and in 2015 worldwide there was around 2.3 million living with both HCV and HIV. In the UK data studied between 2008 and 2014 showed that around 4% of people with HCV were co infected with HIV. More than 84% of them were male, and 66% were of white ethnicity. Two thirds of those who were co-infected were diagnosed with HIV ≥6 months before HCV [22].

Detainees with disease: Unless they are severely ill, detainees can be managed in custody. Special precautions are only required if they are bleeding. Custody staff should wear gloves if contact with blood is likely. Contaminated bedding should be handled appropriately and the cell cleaned professionally after use. Medication should be continued wherever possible.

Hepatitis D (Delta Agent)

This defective transmissible virus discovered in 1977 requires HBV for its own replication. At least 5% of people with chronic hepatitis B are co-infected with HDV meaning that about 15–20 million people world-wide are infected. High prevalence areas include Central and West Africa, Central and Northern Asia, Vietnam, Mongolia, Pakistan, Japan and Chinese Taipei, the Pacific islands of Kiribati and Nauru, the Middle East, Eastern Europe, the Amazon Basin and Greenland. The number of cases has been falling since the 1980s with the introduction of a successful global hepatitis B immunization program [23].

HDV is associated with acute (co-infection) and chronic hepatitis (superinfection) and can exacerbate pre-existing liver damage caused by HBV in as little as 5 years. The routes of transmission and at-risk groups are the same as for HBV. Staff/victims in contact with a putative exposure and detainees with disease should be

WIT.0043.0086.0358

managed as for HBV. Current guidelines advise treatment with pegylated Interferon-alpha for 28 weeks, but this would not be practical to continue in the custodial setting [23, 24].

Human Immunodeficiency Virus

Epidemiology and Prevalence

HIV was first identified in 1983—2 years after the first reports were made to the CDC Atlanta, GA, of an increased incidence of two unusual diseases (Kaposi's sarcoma and *Pneumocystis carinii* pneumonia) occurring among the gay population in San Francisco. The scale of the virus gradually emerged over the years, and by the end of 2016, there was an estimated 36.7 million people throughout the world living with HIV or AIDS. Over 80% of the world total live in Africa and India [25].

By the end of 2015 the number of people living with HIV in the UK was estimated at 101,200 with around 13,500 (13%) unware of their infection. The overall HIV prevalence in the UK is about 0.16% [26].

The number of new diagnoses has continued to fall over the past 10 years with a marked decrease in 2016 and 2017. From 2017 data the total number of new HIV diagnoses was 4363 with most among men who have sex with men (2330). This still represents a 30% drop since 2015. Around 1400 new cases were diagnosed in heterosexual woman and around 1000 new cases in heterosexual men. PWIDs have remained consistently low with only 140 new diagnoses being made in 2017 [27]. This equates to about 1 in 100 PWID who are living with HIV. Most are accessing antiviral treatment but are more likely to be diagnosed late [8].

The proportion of people being diagnosed at a late stage of infection (CD4 count <350 cells/mm^3 at diagnosis) remains high at around 40%. This is significant as when a diagnosis is made late there is a tenfold increased risk of death within a year of diagnosis and an increased risk of onward transmission. The highest risk group for late diagnosis was black African heterosexual men (69%) and the lowest rates were among gay and bisexual men (33%) [27].

UK data collected in 2017 showed that 98% of persons seen for HIV care are receiving anti-retroviral therapy (ART) compared with 79% in 2008 (Table 10.4).

Table 10.4 Persons seen for HIV care in the UK by ethnicity and probable routes of exposure (2017)

	MSM (%)	Heterosexual (%)	IDU (%)	Mother to child (%)
White	84	25.6	87.5	9.3
Black African	1.7	56.9	2	70.9
Black Caribbean	1.99	4.06	3.3	1.6
Asian	3.6	3.8	1.8	4.3

Taken from National HIV surveillance data tables [28]

WIT.0043.0086.0359

Window Period for HIV

Following infection with HIV there is a period of time when the person is very infectious but an HIV antibody test could be negative. This is known as the window period, which for a fourth generation antigen/antibody test is about 4 weeks. At this time about 95% of patients will test positive. By 12 weeks the figure is 99.9%. The earliest point where antibodies could be detected is 2 weeks.

PCR can be used to measure the viral load and this can be detected as early as 7 days after infection. The higher the viral load the more likely the person will have seroconversion symptoms. At the same time as the viral load becomes detectable the p24 viral antigen is also present in the blood. A negative p24 and viral load early on in infection do not mean that the person has not got HIV. Usually an antibody test is conducted 4 weeks after exposure and if it is negative it is repeated at 12 weeks.

During the acute phase of the infection, between 50–80% of people experience a sero-conversion "flu-like" illness. In some people the symptoms are so mild that they may be missed and in 20% they get nothing at all. The individual is infectious at this time, as viral antigen (p24) and viral particles are present in the blood. As antibodies start to form, the virus disappears and the individual enters the latent phase. They are non-infectious and remain well for a variable period of time (7–15 years). Development of the AIDS marks the terminal phase of disease. Viral antigen re-emerges and the individual is once again infectious. With the development of effective ART patients who take a combination of drugs are very unlikely to develop AIDS. Treatment has changed HIV from being a fatal disease to being a chronic and very manageable condition.

Routes of Transmission

Parenteral transmission includes needle stick injuries, bites, unscreened blood transfusions, tattooing, acupuncture and dental procedures where equipment is inadequately sterilised. Risk of transmission is increased with deep penetrating injuries with hollow bore needles that are visibly bloodstained, especially when the device has previously been in the source patient's (contact) artery or vein. Other routes include mucous membrane exposure, (eyes, mouth and genital mucous membranes) and contamination of broken skin.

The higher the viral load in the contact, the greater the risk of transmission. This is more likely at the terminal stage of infection unless the patient is being treated. HIV is transmitted mainly through blood or other body fluids that are visibly bloodstained with the exception of semen, vaginal fluid and breast milk. Saliva alone is most unlikely to transmit infection. Therefore, people who have sustained penetrating bite injuries can be reassured that they are not at risk providing the contact was not bleeding from the mouth at the time.

WIT.0043.0086.0360

Risk of Seroconversion

The risk from a single percutaneous exposure from a hollow bore needle is low (<3 in 1000) and a single mucocutaneous exposure is even less likely to result in infection (<1 in 1000).

The risk from sexual exposure varies, though it appears that there is a greater risk with receptive anal intercourse compared with receptive vaginal intercourse [29, 30] (see Table 10.5).

Body Fluids Containing HIV

High-risk fluids include blood, semen, vaginal fluid and breast milk. There is little or no risk from saliva, urine, vomit or faeces unless they are visibly bloodstained. Other fluids that constitute a theoretical risk include CSF, peritoneal, pleural, synovial or pericardial fluid.

Management in Custody of Staff/Victims in Contact with Disease

Management in custody of staff/victims in contact with disease includes following the immediate management flow chart (Fig. 10.1) and contacting the designated hospital/specialist with details of the exposure. Where possible, obtain a blood sample from the contact. Like HBV and HCV, blood samples taken for HIV testing can only be taken with informed consent in the United Kingdom. There is no need to go into details about the meaning of the test, but the contact should be encouraged to attend the genito-urinary department (or similar) of the designated hospital to discuss the test results. Should the contact refuse to provide a blood sample, then any

Table 10.5 Risks of HIV transmission from a known HIV positive individual

Type of exposure	Estimated risk of HIV transmission[a]
	Per exposure (%)
Blood transfusion (one unit)	90–100
Sharing injection equipment	0.63

R recommended, *NR* not recommended

information about their lifestyle, ethnic origin, state of health, etc. may be useful for the specialist to decide whether post-exposure prophylaxis (PEP) should be given to the recipient. Where saliva only is involved in a penetrating bite injury, there is every justification to reassure the recipient that there is little risk of acquiring HIV. However, it is still wise to take advice from a specialist. Table 10.6 shows the various exposures and whether post exposure prophylaxis (PEP) would be recommended.

In the UK, the current recommended regime for PEP is one Truvada tablet (254 mg tenofovir and 200 mg emtricitabine) once a day plus raltegravir twice a day for 28 days [30].

Treatment should be started as soon as possible after exposure and ideally within 24 h, but it can be considered for up to 72 h. It is usually given for 4 weeks unless the contact is subsequently identified as HIV negative or the recipient develops tolerance or toxicity occurs.

In the UK high risk countries or groups would include men who have sex with men (MSM) and PWID from high risk countries e.g. Eastern Europe, and Central Asia. It would also include individuals who have immigrated to the UK from high risk countries particularly sub Saharan Africa.

If the source states that they are HIV positive, and are being treated, then it is important to establish what the viral load, resistance profile and treatment history is. For the recipient not to need PEP, if the viral load of the source is reported as undetectable it has to have been less than 200 copies/mL for at least 6 months. Where

WIT.0043.0086.0362

there is any uncertainty about the results or doubt as to compliance with ART then PEP should be given after unprotected anal intercourse. Routine blood test monitoring is not recommended for raltegravir based PEP if baseline bloods are normal and there is no clinical indication.

Other useful information that may influence the decision whether to treat with the standard regime or use alternative drugs include interaction with other medications that the recipient may be taking or if the contact has been on anti-retroviral therapy which has not been sustained or drug resistance is suspected.

PEP is not considered for exposure to low or no risk fluids through any route, nor where the source is unknown, e.g. a discarded needle. Despite the appropriate use and timing of PEP, there have been reports of failure [31, 32].

Management in Custody of Detainees with HIV

Unless they are severely ill, they can be kept in custody. Every effort should be made to continue any treatment they may be receiving. Apply standard precautions when dealing with the detainee and ensure that contaminated cells and/or bedding are managed appropriately.

Transmission Through Contact with Lesions or Organisms

Varicella (Chicken Pox)

Epidemiology and Prevalence

Cases of this highly infectious disease occur throughout the year, but are more frequent in winter and early spring. This seasonal endemicity appears to be blurring with global warming but in the UK it reaches a peak between March and May. In the UK, the highest prevalence occurs in the 4–10 years age group. Ninety percent of the population over the age of 40 are immune [33]. A similar prevalence has been reported in other parts of Western Europe and the USA. In South East Asia, Varicella is mainly a disease of adulthood [34]. Therefore, people born in these countries who have moved to the UK are more likely to be susceptible to chicken pox.

There is a strong correlation between a history of chicken pox and serologic immunity (97–99%). Most adults born and living in industrialised countries with an uncertain or negative history of chicken pox are also seropositive (70–90%). In March 1995, a live-attenuated vaccine was licensed for use in the USA and a policy for vaccinating children and susceptible healthcare personnel was introduced. In the summer of 2002 in the UK, GlaxoSmithKline launched a live-attenuated vaccine called Varilrix. In December 2003, the Department of Health, following advice from the Joint Committee on Vaccination and Immunisation (JCVI), recommended that the vaccine be given for non-immune healthcare workers who are likely to have direct contact with individuals with chicken pox. Any healthcare worker with no previous history of chicken pox should be screened for immunity, and if no

WIT.0043.0086.0363

antibodies are found, they should receive two doses of vaccine 4–8 weeks apart. The other group of people who would be considered for vaccination are close contacts (e.g. family members) of patients with weakened immune systems who would be at high risk of developing complications.

The vaccine is still not currently recommended for children in the UK and should not be given during pregnancy. The rationale behind not vaccinating in the UK stems from the concern that if children are vaccinated then the virus is not circulating. This means that children who have not been vaccinated will be more susceptible as adults when the disease can be more serious or in pregnancy when the baby can be harmed. As adults, being exposed to natural disease from infected children boosts immunity and protects the adults from developing shingles. Therefore it is likely that the number of cases of shingles would rise if children were routinely vaccinated. Other countries, including the USA and Australia, disagree with this policy and vaccinate their children.

Incubation Period and Symptoms

Following an incubation period of 7–21 days (this may be shorter in the immunocompromised), there is usually a prodromal "flu-like" illness which lasts 1–2 days before the onset of the rash. This coryzal phase may be absent particularly in young children. The lesions typically appear in crops; rapidly progressing from red papules through vesicles to open sores that crust over and separate by 10 days. They appear on the face and scalp and spread on to the trunk and then the limbs. The distribution of the rash is centripetal, i.e. more over the trunk and face than on the limbs which is the converse of small pox. In adults, the disease is often more severe with lesions involving the scalp and mucous membranes of the oropharynx.

Complications

In children, the disease is often mild, unless they are immunocompromised, so are unlikely to experience complications. In adults (defined as 15 years or older), the picture is rather different [35]. Secondary bacterial infection is common, but rarely serious. There is an increased likelihood of permanent scarring. Hemorrhagic chickenpox typically occurs on the 2nd or 3rd day of the rash. Usually, this is limited to bleeding into the skin, but life-threatening melaena, epistaxis or hematuria can occur.

Varicella pneumonia ranges from patchy lung consolidation to overt pneumonitis and occurs in 1 in 400 cases [36]. It can occur in previously healthy individuals (particularly adults), but the risk is increased in those who smoke. Immunocompromised people are at the greatest risk of developing this complication. It runs a fulminating course and is the commonest cause of Varicella-associated death.

Fibrosis and permanent respiratory impairment may occur in those who survive. Any suspicion of lung involvement is an indication for immediate treatment and any detainee or staff member should be sent to hospital. Involvement of the CNS includes a variety of conditions including meningitis, Guillain–Barre and encephalitis. The latter is more common in the immunocompromised and can be fatal.

Complications can also occur in pregnancy—see At-risk groups.

WIT.0043.0086.0364

Period of Infectivity

This is taken as 1–3 days before the first lesions appear to the end of new vesicle formation and the last vesicle has crusted over. This typically is 5–7 days after onset, but may last up to 14 days. It is more likely to be prolonged in immunocompromised people.

Routes of Transmission

The primary route is through direct contact with open lesions of chicken pox. However, it is also spread through aerosol or droplets from the respiratory tract. Chicken pox may also be acquired through contact with open lesions of shingles (Varicella zoster), but this is less likely as shingles is less infectious than chicken pox. The secondary infection rate from a household contact with chicken pox can be as high as 90%.

At-Risk Groups

Non-immune individuals are at risk of acquiring disease. Approximately 10% of the adult population born in the UK and <5% of adults in the USA fall into this category. Therefore, it is more likely that if chicken pox is encountered in the custodial setting, it will involve people born outside the UK (in particular South East Asia) or individuals who are immunocompromised and have lost immunity. Non-immune pregnant women are at risk of developing complications.

Pneumonia can occur in up to 10% of pregnant women with chicken pox and the severity appears to be increased in later gestation [37]. They can also transmit infection to the unborn baby [38]. If infection is acquired in the first 20 weeks, there is <3% chance of it leading to congenital Varicella syndrome. This includes limb hypoplasia, microcephaly, cataracts and growth retardation. Mortality estimates are between 1–2%.

Infection in the last trimester can lead to neonatal Varicella unless more than 7 days elapse between onset of maternal rash and delivery when antibodies have time to cross the placenta leading to either mild or inapparent infection in the newborn. In this situation, Varicella immunoglobulin (VZIG) should be administered to the baby as soon as possible after birth [39].

Management in Custody

Staff with chicken pox should stay off work until the end of the infective period (approximately 7–14 days). Those in contact with disease who are known to be non-immune or who have no history of disease should contact the designated occupational health physician. A significant contact would be considered as being in the same room for at least 15 min.

Detainees with visible disease should not be kept in custody if at all possible (especially pregnant women). If this is unavoidable, then non-immune or immunocompromised staff should avoid entering the cell or having close contact with the detainee.

Non-immune immunocompromised or pregnant individuals exposed to chicken-pox should seek expert medical advice for the administration of VZIG. Aciclovir (or

WIT.0043.0086.0365

similar antiviral agent) should be given as soon as possible to immunocompromised people with chicken pox. It should also be considered for anyone over 15 years old who is non immune as they are more likely to develop complications. Immunosuppressed patients who have detectable varicella antibodies will not need VZIG. Second attacks of chicken pox can occur in such people but this is most likely to be due to a fault in cell-mediated immunity.

Do not give ibuprofen as this can cause serious skin infections. Do not give aspirin to under 16 year olds with chicken pox as this can lead to Reyes syndrome which is a serious condition that causes swelling to the liver and the brain. Anyone suspected of severe complications should be sent straight to hospital.

Herpes Zoster (Shingles)

Epidemiology

After chicken pox, the varicella zoster virus lies dormant in the dorsal root or cranial nerve ganglia, but may reactivate and re-emerge typically involving one dermatome [40]. The site of involvement depends on the sensory ganglion initially involved. Shingles is more common over the age of 50, but it can occur in children and is very common in the immunosuppressed at any age. The latter are also more susceptible to secondary attacks and involvement of more than one dermatome. Bilateral zoster is even rarer, but is not associated with a higher mortality.

In the UK, there is an estimated incidence of 1.2–3.4 per 1000-person years [41].

Symptoms

There may be a prodromal period of paresthesia and burning or shooting pains in the involved segment. This is usually followed by the appearance of a band of vesicles. Rarely, the vesicles fail to appear and only pain is experienced. This is known as *zoster sine herpete*. In individuals who are immunocompromised, disease may be prolonged and dissemination may occur but is rarely fatal. The overall fatality rate is estimated as 1/1000 persons over 70 years old.

Shingles in pregnancy is usually mild. The fetus is only affected if viremia occurs before maternal antibody has had time to cross the placenta.

Complications

The most common complication of shingles is post-herpetic neuralgia (PHN) occurring in about 10% of cases. It is defined as pain lasting more than 120 days from rash onset [42]. It is more frequent in people over 50 and can lead to depression as the pain can be very debilitating and is mostly unresponsive to standard pain killers. Other drugs such as pregabalin and amitryptiline may help to alleviate symptoms. Infection of the brain can lead to encephalitis, involvement of motor neurones leading to ptosis, paralysis of the hand, facial palsy or contralateral hemiparesis. Involvement of the oculomotor division of the trigeminal ganglion can cause serious eye problems including corneal scarring.

Period of Infectivity

Shingles is far less infectious than chicken pox and is only considered to be infectious up to 3 days after lesions appear.

Routes of Transmission

Shingles is only infectious following prolonged contact with lesions. Unlike chickenpox, airborne transmission is not a risk.

At-Risk Groups

Individuals who are immunocompromised may reactivate the dormant virus and develop shingles. People who have not had primary Varicella are at risk of developing chicken pox following prolonged direct contact with shingles.

Despite popular belief, it is untrue that immunocompetent people who have had chicken pox develop shingles when in contact with either chicken pox or shingles. Such occurrences are merely coincidental unless immunity is lowered.

Management in Custody

Staff with shingles should stay off work until the lesions are healed unless they can be covered. Staff who have had chicken pox are immune (including pregnant women) and are therefore not at risk. If they are non-immune (usually accepted as those without a history of chickenpox), they should avoid prolonged contact with detainees with shingles. Pregnant non-immune women should avoid contact altogether.

Detainees with disease may be kept in custody and any exposed lesions should be covered. It is well documented that prompt treatment attenuates the severity of the disease, reduces the duration of viral shedding, hastens lesion healing, and reduces the severity and duration of pain. It also reduces the likelihood of developing post-herpetic neuralgia [43]. Prompt treatment with Famciclovir (500 mg tds for 7 days, for example) or acyclovir (800 mg five times a day for 7 days) should be initiated if the onset is 3 days or less. It should also be considered after this time if the detainee is over 50. Pregnant detainees with shingles can be reassured that there is minimal risk for both the mother and the unborn child. Expert advice should be sort before initiating treatment for the mother.

In the UK Zostavax (a live vaccine for shingles) was introduced in September 2013 as a single dose of vaccine for adults aged 70 on 1st September 2013 and aged 79 in the first year as part of a phased catch up. Data from the first 3 years of the program show that there has been a significant reduction in the number of cases of shingles and PHN despite the fact that the vaccine is only about 50% effective [44].

Shingrix is an inactivated shingles vaccine that has been introduced in the USA. This vaccine is given as a two dose course and is reported as being over 90% effective. The uptake has been so great that there have been vaccine shortages while the manufacturers catch up with the unprecedented demand. It has yet to be introduced into the UK.

WIT.0043.0086.0367

Scabies

Epidemiology

This tiny parasitic mite (*Sarcoptes scabiei*) has infested humans for over 2500 years. Experts estimate that in excess of 300 million cases occur worldwide each year. The female mite burrows into the skin especially around the hands, feet and male genitalia, in about 2.5 min. Eggs are laid and hatch into larvae that travel to the skin surface as newly developed mites.

Symptoms

The mite causes intense itching which is often worse at night and is aggravated by heat and moisture. The irritation spreads outside the original point of infection due to an allergic reaction to mite feces. This irritation may persist for about 2 weeks after treatment, but can be alleviated by antihistamines.

Crusted scabies is a far more severe form of the disease. Large areas of the body may be involved. The crusts hide thousands of live mites and eggs making them difficult to treat. This so-called Norwegian scabies is more common in the elderly or the immunocompromised, especially those with untreated HIV.

Incubation Period

Following a primary exposure, it takes about 2–6 weeks before the onset of itching. However, further exposures reduce the incubation time to around 1–4 days.

Period of Infectivity

Without treatment, this is assumed to be indefinite. With treatment, the person should be considered infectious until the mites and eggs are destroyed—usually 7–10 days. Crusted scabies is highly infectious.

Management in Custody

Since transmission is through direct skin-to-skin contact with an infected case, gloves should be worn when dealing with individuals suspected of infestation. Usually prolonged contact is needed, unless the person has crusted Scabies where transmission occurs more easily. The risk of transmission is much greater in households where repeated or prolonged contact is likely.

Since mites can survive in bedding of clothing for up to 24 h, gloves should also be worn when handling these items. Bedding should be treated by washing at a temperature of at least 50 °C. Professional cleaning of the cell is only warranted in cases of crusted scabies.

Treatment

The preferred treatment for scabies is either Permethrin cream (5%) or aqueous Malathion (0.5%) [45]. Either treatment has to be applied to the whole body and should be left on for at least 8 h in the case of permethrin and 24 h for Malathion before washing off. Lindane is no longer considered the treatment of choice, as there may be complications in pregnancy [46].

Treatment in custody may not be practical, but should be considered when the detainee is thought to have Norwegian scabies.

Head Lice

General Information

Like scabies, head lice occur worldwide and are found in the hair close to the scalp. The eggs or nits cling to the hair and are difficult to remove, but are not harmful. If you see nits then you can be sure that lice are also present. The latter are best seen when the hair is wet. The lice bite the scalp and suck blood causing intense irritation and itching.

Route of Transmission

They can only be passed from direct hair to hair contact.

Management in Custody

It is only necessary to wear gloves when examining the head for whatever reason. The cell does not need to be cleaned after use, since the lice live on or near skin. Bedding may be contaminated with shed skin so should be handled with gloves and laundered or incinerated.

The presence of live lice is an indication for treatment either by physical removal with a comb or the application of an insecticide. The latter may be more practical in custody. 0.5% aqueous Malathion should be applied to dry hair and washed off after 12 h. The hair should then be shampooed as normal.

Crabs or Body Lice

General Information

They are more commonly found in the pubic, axillary, chest and leg hair. However, eyelashes and eyebrows may also be involved. They are associated with people who do not bath or change clothes regularly. The person usually complains of intense itching or irritation.

Routes of Transmission

The main route is from person to person by direct contact, but eggs can stick to fibers so clothing and bedding should be handled with care (see section below).

Management in Custody

Staff should always wear gloves if they are likely to come into contact with any hirsute body part. Clothing or bedding should be handled with gloves and either laundered or incinerated.

Treatment of a detainee in custody is good in theory but probably impractical as the whole body has to be treated.

Fleas

General Information

Fleas lay eggs on floors, carpets and bedding. In the UK, most fleabites come from cats or dogs. The eggs and larvae fleas can survive for months and are reactivated in

WIT.0043.0086.0369

response to animal or human activity. Since animal fleas jump off humans after biting, most detainees with fleabites will not have fleas, unless they are human fleas.

Management in Custody

Treatment is only necessary if fleas are seen. After use, the cell should be vacuumed and cleaned with a proprietary insecticide. Any bedding should be removed wearing gloves, bagged and either laundered or incinerated.

Bedbugs

General Information

Bedbugs live and lay eggs on walls, floors, furniture and bedding. If you look carefully, fecal tracks may be seen on hard surfaces. If they are present for long enough, then they emit a distinct odor. Bedbugs are rarely found on the person, but may be brought in on clothing or other personal effects.

Symptoms

Bedbugs bite at night and can cause sleep disturbance.

Management in Custody

The detainee does not need to be treated, but the cell should be deemed out of use until it can be vacuumed and professionally cleaned with an insecticide solution. Any bedding or clothing should be handled with gloves and disposed of as appropriate.

Methicillin-Resistant *Staphylococcus aureus*

Epidemiology

Staphylococcus aureus is commonly carried on the skin or in the nose of healthy people. Approximately 25–30% of the population is colonized with the bacteria, but remain well [47]. From time to time, the bacteria cause minor skin infections that usually do not require antibiotic treatment. However, more serious problems can occur, e.g. infection of surgical wounds, drug injection sites, osteomyelitis, pneumonia or bacteremia. Over the last 50 years, the bacteria have become increasingly resistant to penicillin-based antibiotics [48] and in the last 20 years to an increasing number of alternative antibiotics. These multi-resistant bacteria are known as methicillin-resistant *S. aureus* (MRSA).

MRSA is prevalent worldwide. Like non-resistant staphylococci, it may remain undetected as a reservoir in colonized individuals, but can also produce clinical disease. It is more common among the elderly, debilitated or immunocompromised people or those with open wounds. Clusters of skin infections with MRSA have been reported among injecting drug users since 1981 in America [49, 50] and more recently similar strains have been found in the UK in PWIDs in the community [51]. This may have particular relevance for the healthcare professional when dealing

WIT.0043.0086.0370

with injecting drug users' ulcers or abscesses. Immunocompetent people rarely get MRSA and should not be considered at risk. Between April 2003 and December 2008, there were 74 recorded cases of a community-acquired MRSA in injecting drug users in England and Wales [52]. A study conducted from the CDC in Atlanta looked at data from injecting drug users between 2005 and 2016. The data showed that PWID are 16.3 × more likely to develop invasive MRSA infections than others.

Data from 2016 in the UK from the mandatory enhanced surveillance showed that 13% of the Methiciliin Sensitive Staphylcoccus Aureus (MSSA) bacteremia and 8.1% of the MRSA bacteremias were associated with injecting drug use [53]. This has increased since 2011 from 6.9% for MSSA and 1.6% for MRSA.

In 2014 in Bristol there was an increase in the number of severe MRSA infections among PWID. A study showed that 8.7% of PWID in Bristol were carriers compared with 1–4% for the UK population in general. The rise in cases was thought to be due to a specific clone and to the increase in injecting outside and into the groin [53].

Route of Transmission

The bacteria are usually spread via the hands of staff after contact with colonized or infected detainees or devices, items (e.g. bedding, towels, soiled dressings) or environmental surfaces that have been contaminated with MRSA-containing body fluids.

Management in Custody

With either known or suspected cases (consider all abscesses/ulcers of injecting drug users as infectious), standard precautions should be applied. Staff should wear gloves when touching mucous membranes, non-intact skin, blood or other body fluids or any items that could be contaminated. They should also be encouraged to wash hands with an antimicrobial agent whether or not gloves have been worn. After use, gloves should be disposed of in a yellow "hazard" bag and not allowed to touch surfaces. Masks and gowns should only be worn when carrying out procedures that generate aerosols of blood or other body fluids. Since this is an unlikely scenario in the custodial setting, they should not be necessary. Gloves should be worn when handling bedding or clothing and all items should be disposed of in the appropriate manner. Any open wounds should be covered as soon as possible. The cell should be cleaned professionally after use if there is any risk that it has been contaminated.

Other Bacteria Associated with Abscess Formation in Injecting Drug Users

Epidemiology

Over the last decade, there has been an increasing awareness of the bacterial flora colonizing injection sites that may potentially lead to life-threatening infection [54].

WIT.0043.0086.0371

In 1997, a sudden increase in needle abscesses caused by a clonal strain of Group A *Streptococcus* (GAS) was reported among hospitalized intravenous drug users (IDUs) in Berne, Switzerland [55]. A recent study in the UK showed that the predominant isolate is *S. aureus*, with *Streptococcus* species forming just under one fifth (50% *beta-hemolytic* streptococci) [56].

There have also been reports of both non-sporing and sporing anaerobes (e.g. *Bacteroides* and *Clostridia* species including *Clostridium botulinum*) [57, 58]. In terms of numbers, in 2003–2004, injecting drug use was one of the most important risk factors for Group A streptococcal infection in the United Kingdom accounting for 20%. Over subsequent years the number of cases fell [52]. However, in 2016/17 there has been an increase in invasive Group A Streptococcal infections (iGAS) amongst homeless people and PWID in England and Wales. In Brighton, Gloucestershire, Bristol and London there was an emm66 cluster and more recently an emm99 cluster in Bournemouth which is spreading more widely [53].

In 2000, laboratories in Glasgow were reporting isolates of *C. novyi* among IDUs with "serious unexplained illness". By 12 June 2000, a total of 42 cases (18 definite and 24 probable) had been reported. A definite case was defined as an IDU with both severe local and systemic inflammatory reactions. A probable case was defined as an IDU who presented to hospital with an abscess or other significant inflammation at an injecting site and had either a severe inflammatory process at or around an injection site or a severe systemic reaction with multiorgan failure and a high white cell count [59].

In the UK, the presence of *C. botulinum* in infected injection sites is a relatively new phenomenon. Up to the end of 1999, there were no cases reported to the Public Health Laboratory Service (PHLS). Since then the number has increased with a total of 13 cases in the UK and Eire being reported since the beginning of 2002. It is thought that these cases are associated with contaminated batches of heroin. Simultaneous injection of cocaine increases the risk by encouraging anaerobic conditions. Anaerobic flora in wounds may have serious consequences for the detainee but the risk of transmission to staff is virtually non-existent. By the end of 2008, a cumulative total of 132 suspected cases had been reported from the United Kingdom, with 86% of cases occurring in England. Four cases were reported in 2008 alone [52]. In 2016 wound botulism still continues to be a problem albeit rare with seven cases being reported and one case of confirmed tetanus [8].

In December 2009, two injecting drug users in Scotland died from anthrax contaminated heroin. Following this, two further deaths occurred in England in February 2010. An alert was issued first by the Department of Health and then, by the National Treatment Agency warning any drug user of the possible risks. Spores from the bacillus anthracis can contaminate heroin without any obvious signs. Anthrax can be acquired by injecting, smoking or inhaling heroin. Obvious symptoms include excessive swelling and redness at injection sites, fever, headache or shortness of breath when the heroin is smoked. Users are advised to go straight to the Emergency Department if they are at all worried. Such infections with spore forming bacteria

WIT.0043.0086.0372

will always occur from time to time. Healthcare professionals should be mindful at all times. There were no reported cases of anthrax in 2016.

Management in Custody

Staff should be reminded to wear gloves when coming into contact with detainees with infected skin sites exuding pus or serum and that any old dressings found in the cell should be disposed of into the yellow bag marked "clinical waste" in the medical room. Likewise, any bedding should be bagged and laundered or incinerated after use. The cell should be deemed out of use and professionally cleaned after the detainee has gone.

The healthcare professional managing the detainee should clean and dress open wounds as soon as possible to prevent the spread of infection. It may also be appropriate to start a course of antibiotics if there is abscess formation, signs of cellulitis and/or the detainee is systemically unwell. However, infections can often be low-grade because the skin, venous and lymphatic systems have been damaged by repeated penetration of the skin. In these cases, signs include lymphoedema, swollen lymph glands and darkly pigmented skin over the area. Fever may or may not be present, but septicemia is uncommon unless the individual is immunocompromised (e.g. HIV positive). Co-Amoxiclav is the preferred treatment of choice as this covers majority of staphylococci, streptococci and anaerobes (the dose used is dependent on the degree of infection).

Necrotizing fasciitis and septic thrombophlebitis are rare but life-threatening complications of intravenous drug use. Any detainee suspected of either of these needs hospital treatment. Advice about harm reduction should also be given. This includes encouraging drug users to smoke rather than inject or at least to advise them to avoid injecting into muscle or skin. Although most injecting drug users are aware of the risk of sharing needles, they may not realize that sharing any drug paraphernalia could be hazardous. Advice should be given to use the minimum amount of citric acid to dissolve the heroin as the acid can damage the tissue under the skin allowing bacteria to flourish. Drugs should be injected at different sites using fresh works for each injection. This is particularly important when "snowballing" as crack cocaine creates an anaerobic environment. Medical help should be requested if any injection site become painful and swollen or shows signs of pus collecting under the skin. Much work has been done to vaccinate PWID against hepatitis B but there is always an opportunity to check their status and encourage them to get vaccinated if they have not had it. Hepatitis A vaccine should also be encouraged as cases of the disease do get reported in PWID.

Another serious but relatively rare problem is the risk from broken needles in veins. Embolization can take anything from hours to days or even longer if it is not removed. Complications may include endocarditis, pericarditis or pulmonary abscesses [60, 61]. PWID should be advised to seek medical help as soon as possible, and should such a case present in custody, then the detainee should be sent straight to hospital.

WIT.0043.0086.0373

Management of Human and Dog Bites

The HCP may encounter bites in four circumstances:

1. During the examination of victims of assault (both children and adults) where presentation is more likely to be late
2. Among police officers bitten during the arrest of a detainee
3. In detainees during the arrest if dogs have been used
4. Where detainees have been involved in a fight either around the time of arrest or earlier

A detailed forensic examination of bites is given in Chap. 4. With any bite that has penetrated the skin, the goals of therapy are to minimize soft tissue deformity and to prevent or treat infection.

Epidemiology

In the UK and USA, dog bites represent approximately three-quarters of all bites presenting to Emergency departments [62]. A single dog bite can produce up to 220 psi of crush force in addition to the torsional forces as the dog shakes its head. This can result in massive tissue damage. Human bites may cause classical bite marks or puncture wounds (e.g. impact of fists on teeth) resulting in crush injuries.

Rates and Risks of Infection

An estimated 10–30% of dog bites and 9–50% of human bites lead to infection. Compare this with an estimated 1–12% of non-bite wounds managed in Emergency Departments.

The risk of infection is increased with puncture wounds, hand injuries, full thickness wounds, wounds requiring debridement, and those involving joints, tendons, ligaments or fractures.

Co-morbid medical conditions such as diabetes, asplenia, chronic edema of the area, liver dysfunction, the presence of a prosthetic valve or joint, and an immunocompromised state may also increase the risk of infection.

Other Complications of Bites

Infection may spread beyond the initial site, leading to septic arthritis, osteomyelitis, endocarditis, peritonitis, septicemia and meningitis. Inflammation of the tendons or synovial lining of joints may also occur. If enough force is used, bones may be fractured or the wounds may be permanently disfiguring.

Initial Management

Encourage the wound to bleed unless it is already bleeding and irrigate with warm running water. Assessment as to whether hospital treatment is necessary should be made as soon as possible. Always refer if the wound is bleeding heavily or fails to stop when pressure is applied. Penetrating bites involving arteries, nerves, muscles, tendons, the hands or feet or resulting in a moderate-to-serious facial wound, or crush injuries also require immediate referral.

WIT.0043.0086.0374

If management within custody is appropriate, then ask about current tetanus vaccine status, HBV vaccination status and known allergies to antibiotics.

A full forensic documentation of the bite should be made as detailed in Chap. 4.

Note if there are clinical signs of infection such as erythema, edema, cellulitis, purulent discharge, or regional lymphadenopathy. Cover the wound with a sterile, non-adhesive dressing. Wound closure is rarely advised in primary care and is not generally recommended as data suggest that this may increase the risk of infection. This is particularly relevant for non-facial wounds, deep puncture wounds, bites to the hand, clinically infected wounds, and those occurring more than 6–12 h before presentation. Head and neck wounds in cosmetically important areas may be closed if less than 12 h old and not obviously infected. This should only be done in a tertiary setting by an appropriately trained health care professional.

Pathogens Involved

1. Bacteria
   - Dog bites—*Pasteurella canis, P. multocida, S. aureus*, other staphylococci, *Streptococcus* species, *Eikenella corrodens*, *Corynebacterium* species and anaerobes including *Bacteroides fragilis* and *C. tetani*.
   - Human bites—*Streptococcus* species, *S. aureus, E. corrodens*, and anaerobes including *Bacteroides* (often penicillin resistant), peptostreptococci species, and *C. tetani*. TB and syphilis may also be transmitted.
2. Viruses
   - Dog bites—Outside of the UK, Australia and New Zealand, rabies should be considered. In the USA, domestic dogs are mostly vaccinated against rabies [63], and police dogs have to be vaccinated, so the most common source is from racoons, skunks and bats.
   - Human bites—HBV, HCV, HIV, and herpes simplex.

Antibiotic Prophylaxis

Prophylactic antibiotics should be prescribed for all human and cat bites less than 72 h old even if there is no sign of infection. For other animal bites then antibiotics should be prescribed if the bite involves the hand, foot and face, joints, tendons or where there are suspected fractures. Antibiotics should also be prescribed for people who are at increased risk of infection e.g. diabetes, asplenia, cirrhosis, immunosuppressed, or who have a prosthetic joint or valve.

Co-amoxiclav (amoxycillin and clavulanic acid) is the first choice for both prophylaxis and treatment and should be given for 7 days. For adults, the recommended dose is 500/125 mg tds and for children 40 mg/kg tds (based on amoxycillin component). If the individual is known or suspected to be allergic to penicillin, then a tetracycline (e.g. doxycycline 100 mg bd) and metronidazole (500 mg tds) or erythromycin (or clarithromycin) and metronidazole can be used. Specialist advice should be sort for children who are penicillin allergic and for pregnant women.

Anyone with severe infection or who is clinically unwell should be referred to hospital. Tetanus vaccine should be given if the primary course or last booster was more than 10 years ago. Human tetanus immunoglobulin should be considered for tetanus-prone wounds (e.g. soil contamination, puncture wounds, signs of

devitalized tissue, or for wounds sustained more than 6 h old). If the person has never been immunized or is unsure of their tetanus status, then a full three-dose course, spaced at least a month apart, should be given.

Management of Suspected Viral Infections from Human Bites

Penetrating bite wounds that involve only saliva may present a risk of HBV if the perpetrator belongs to a high-risk group. For management see "Disease Prevention" and "Management in Custody" in section "Hepatitis B". HCV and HIV are only a risk if blood is involved. The relevant management is dealt with in "Management in Custody" in section "Hepatitis C" and "Management in Custody of Staff/Victims in Contact with Disease" in section "Human Immunodeficiency Virus". Consultation with a virologist or communicable diseases doctor should be sought at the earliest opportunity.

Infections Transmitted Through the Respiratory Route

General Information

Respiratory tract infections are common, are usually mild and self-limiting, although they may require symptomatic treatment with paracetamol or a non-steroidal anti-inflammatory. These include the common cold (80%—rhinoviruses and 20%—coronaviruses), adenoviruses, influenza and parainfluenza, and during the summer and early autumn—enteroviruses. Special attention should be given to asthmatics or the immunocompromised detainee, as infection in these people may be more serious particularly if the lower respiratory tract is involved.

The following section includes respiratory pathogens of special note as they may pose a risk to both the detainee and/or staff who come into close contact.

Meningococcal Meningitis (*Neisseria meningitidis*)

General Information and Epidemiology

There are six meningococcal capsular groups of *Neisseria meningitidis*: A, B, C, W135 X and Y that are responsible for nearly all invasive infections in humans. The prevalence of the different types varies from country to country. In the UK nasopharynx carriage prevalence is around 5% in infants and reaches a peak at around aged 19 of 24%. The rate declines to about 8% in adulthood. The risk of invasive disease following acquisition varies with environmental and host factors. Established carriers rarely get invasive disease.

In 1999 the MenC conjugate vaccine was introduced and vaccination programs over the years have substantially reduced the number of cases in the under 18 s. A secondary benefit of the reduced carriage rate in immunized adolescents was to reduce the number of cases in older age groups. MenC has remained well controlled with 20–30 cases occurring annually over the last 10 years. Of the current cases many occur in people who were born outside the UK and who may not have been vaccinated.

WIT.0043.0086.0376

Cases of MenW were associated with the Hajj pilgrimage in the early 2000 but this has been controlled by the mandatory introduction of MenACWY vaccination for all pilgrims going to Saudi Arabia. Since then MenW have accounted for about 5% of invasive disease until 2010 when cases increased with a peak in 2015/16 of more than 200 cases in that year. The cause was identified as a hypervirulent strain which was responsible for severe disease with high fatality rates in South America, From August 2015 the UK introduced an emergency MenACWY vaccination program for adolescents. The conjugate vaccine is now routinely given to 14 year olds with a catch up for 14–18 years and new university students up to their 25th birthday. This has been effective as by the end of August 2016 there was a 69% decrease of MenW disease in those who left school in the summer of 2015.

MenB disease has declined in the UK over the last 10 years. Around 26% of MenB cases occur in the first year of life with 60% occurring during the first 5 years. A second smaller peak occurs in 15–19 year olds. Since September 2015 MenB vaccine has been incorporated into the UK childhood program and there has already been a fall in the number of cases [64].

Symptoms

Following an incubation period of 3–5 days [65, 66], disease onset may either be insidious with mild prodromal symptoms or florid. Early symptoms and signs include malaise, fever and vomiting. Severe headache, neck stiffness, photophobia, drowsiness and a rash may develop. The rash may be petechial or purpuric and characteristically does not blanche under pressure. Meningitis in infants is more likely to be insidious in onset and lack the classical signs. In approximately 15–20% of cases, septicemia is the predominant feature. Even with prompt antibiotic treatment, the case fatality rate is 3–5% in meningitis and 15–20% in those with septicemia [33]. Meningococcal meningitis and septicemia are statutorily notifiable under health protection legislation in the UK. All cases where a diagnosis of meningococcal disease is suspected should be reported to the Health Protection Team without delay.

Period of Infectivity

A person should be considered infectious until the bacteria are no longer present in nasal discharge. With treatment, this is usually approximately 24 h.

Routes of Transmission

The disease is spread through infected droplets or direct contact from carriers or those who are clinically ill. It requires prolonged and close contact, so is a greater risk for people who share accommodation, utensils, and intimate kissing. It must also be remembered that unprotected mouth-to-mouth resuscitation can also transmit disease but this should never occur in the custody setting where pocket masks and bag valve masks are available.

The risk of illness in close contacts is highest in the first 48 h of disease onset in the index case. The absolute risk of developing a second case of invasive meningococcal disease (IMD) is 1/300 if no chemoprophylaxis is given. Antibiotics are

WIT.0043.0086.0377

given to close contacts of cases to eliminate established carriage and to eradicate carriage in those who have newly acquired the invasive strain.

Transient contact with an index case such as during travel in a plane, bus or car does not justify prophylaxis. European Centre for Disease Prevention and Control (ECDC) guidance indicates flight contact tracing only if there was intense exposure to nasopharyngeal sections. In the USA antibiotic prophylaxis would be recommended for passengers seated next to an index case for more than 8 h.

Management in Custody

Anyone suspected of having meningococcal disease should be sent straight to hospital. Antibiotic prophylaxis is only recommended for those who have had prolonged close contact with a case during the 7 days before the onset of illness, or for those who have had transient close contact but have been directly exposed to large droplets and respiratory excretions around the time of hospitalization. The latter situation may occur in custody with a detainee who is clinically unwell and who coughs into the staff member's face. Respiratory droplets in the eyes is not a case for antibiotics but there is a low risk of meningococcal conjunctivitis. Staff exposed in this way should be advised to seek medical treatment promptly if conjunctivitis develops within 10 days of exposure. Any staff member who thinks they have been exposed should seek advice from their Occupational Health Department or local Health Protection Team.

Ciprofloxacin is the prophylactic antibiotic of choice in the UK, for all age groups and in pregnancy. It is given as a single dose and does not interfere with oral contraceptives and is readily available in pharmacies. In cases of ciprofloxacin hypersensitivity rifampicin is a viable alternative but this requires multiple doses, can inhibit oral contraceptives and is only available through hospital pharmacies. Antibiotic prophylaxis should be given as soon as possible and ideally within 24 h after the diagnosis of the index case. However, antibiotics and vaccine may still be considered up to 28 days later.

Meningococcal vaccination is offered to those at prolonged contact with the index cases. This provides longer term protection and can reduce the chance of late cases. Health care workers or those working in custody suites do not need to be vaccinated routinely because of the low risk of exposure. The threshold for given chemoprophylaxis would however be lowered in those staff members who were immunocompromised [64].

Tuberculosis

Prevalence and Epidemiology

Human tuberculosis (TB) is caused by infection with *Mycobacterium tuberculosis, M. bovis* or *M. africanum*. It is a notifiable disease under legislation specific to individual countries, for example in the UK this comes under the Public Health (Control of Disease) Act 1984. In 1993, the WHO declared TB to be a global emergency with

WIT.0043.0086.0378

an estimated seven to eight million new cases and three million deaths occurring each year, the majority of which were in Asia and Africa.

In 2017 it was estimated that ten million new cases of TB occurred globally (5.8 million men, 3.2 million women and one million children). There were cases in all countries and all age groups but overall 90% were adults (>15) and 9% had concomitant HIV and of those 72% were living in Africa. Two thirds of the TB cases were from eight countries, India, China, Indonesia, Philippines, Pakistan, Nigeria, Bangladesh, and South Africa. Only 6% of global cases were in the WHO European region (3%) and WHO Region of the Americas (3%) [67].

World-wide in 2017 it is estimated that around 558,000 people developed TB that was resistant to Rifampicin (RR-TB) and of these 82% had multi-drug resistant TB (MDR-TB), India, China and the Russian Federation accounted for almost 50% of the cases with India accounting for 24%. Some 8.5% of the MDR-TB cases in 2017 were estimated to have extensively drug resistant TB (XDR-TB).

About 1.7 billion people in the world have latent TB that can be reactivated and are therefore at risk of active disease. This represents just under a quarter of the world population.

TB in England

In 1999 the Enhanced Surveillance system was introduced in England and Wales and in the following year in Northern Ireland. The number of cases of TB rose steadily from 6686 in 2000 to a peak of 8919 cases reported in 2011 after which the numbers started to decline. The overall UK rate in 2017 was reported as 8.4/100,000 down from 14.1/100,000 in 2011. England had the highest rate 9.2/100,000 and Wales the lowest 3.4/100,000. Despite the overall the drop since 2011 England continues to have one of the highest TB rates in Western Europe [68].

Data collected throughout England averaged over a 3 year period of 2015–2017 show that London, Manchester and Birmingham have the highest rates (24.3, 23.4 and 22.8 per 100,000 population respectively). This has been attributed to its highly mobile population, the variety of ethnic groups, a high prevalence of HIV, and the emergence of drug-resistant strains.

A similar picture was initially found in the USA, when there was a reversal of a long-standing downward trend in 1985. However, between 1986 and 1992, the number of cases increased from 22,201 to 26,673 [69]. There were also serious outbreaks of multi-drug-resistant TB (MDR-TB) in hospitals in New York City and Miami [70]. Factors pertinent to the overall upswing included the emergence of HIV, the increasing numbers of immigrants from countries with a high prevalence of tuberculosis, and perhaps more significantly, the stopping of categorical federal funding for control activities in 1972. The latter led to a failure of the public health infrastructure for TB control. Since 1992, the trend has reversed as the CDC transferred most of its funds to tuberculosis surveillance and treatment programs in states and large cities. In 2017 9093 cases were reported to the CDC giving an overall TB rate of 2.8 cases/100,000 persons. More than 50% of all TB was reported in four states (California, Florida, New York and Texas). The TB rate was 14.6 times higher

WIT.0043.0086.0379

in non US born persons than in US born persons and although this represented a decrease in previous years there was only a 0.9% decrease in the non US born persons compared with 7% in those born in the USA. The HIV status was known for 86% of all TB cases reported in 2107 and 5.6% were shown to be co infected with HIV [71].

The acquisition of tuberculosis infection is not necessarily followed by disease as the infection may heal spontaneously. It may take weeks or months before disease becomes apparent or infection may remain dormant for years before reactivation in later life especially if the person becomes debilitated or immunocompromised. Contrary to popular belief, the majority of cases of TB in immunocompetent people pass unnoticed. Of reported cases, 75% involve the lung, while non-respiratory (e.g. bone, heart, kidney, brain) or dissemination (miliary TB) are more common in immigrant ethnic groups and the immunocompromised [72]. They are also more likely to develop resistant strains. In the general population, there is an estimated 10% lifetime risk of tuberculosis infection progressing to disease [73].

In 2017 there were a total of 464,633 cases reported of TB in people living with HIV. This represents 51% of the estimated number of cases indicating the degree of under reporting. This is very significant as TB is more likely to progress to active TB in HIV positive individuals with a greater than 50% lifetime risk [74]. TB can also lead to a worsening of HIV with an increase in viral load [75]. Therefore, the need for early diagnosis is paramount but it can be more difficult as pulmonary TB may present with non-specific features, e.g. bilateral, unilateral or lower lobe shadowing [76].

Symptoms of Pulmonary TB

After an incubation of 4–12 weeks, symptoms may develop (see Table 10.7).

Routes of Transmission

The main route is airborne through infected droplets, but prolonged or close contact is needed. Non-respiratory disease is not considered a risk unless the *Mycobacterium* is aerosolized under exceptional circumstances (e.g. during surgery) or there are open abscesses.

Table 10.7 Symptoms of pulmonary TB

Cough lasting >3 weeks or >2 weeks in endemic countries
Fatigue
Anorexia and weight loss
Fever and night sweats
Mild haemoptysis (rusty colored)
Cough with phlegm
Swollen lymph glands

Period of Infectivity

A person is considered infectious as long as viable bacilli are found in induced sputum. Untreated or incompletely treated people may be intermittently sputum-positive for years.

Following 2 weeks of appropriate treatment, the individual is usually considered as non-infectious. This period may be extended for treatment of MDR-TB or XDR-TB or for those with concomitant HIV. Patient compliance also plays an important factor.

At-Risk Groups

The risk of infection is directly proportional to the degree of exposure. More severe disease occurs in the malnourished, or the immunocompromised (e.g. HIV etc.) and substance misusers.

Immunocompromised people are at special risk of MDR-TB, XDR-TB or *Mycobacterium avium-intracellulare* (MAI) although more recently cases resistant to treatment have been described in immunocompetent people.

Management in Custody

Staff with disease should stay off work for 2 weeks whilst treatment is taking effect. You no longer have to wait to be sputum negative as the bacilli can persist for months even though you are no longer infectious. Staff in contact with disease who have been vaccinated with BCG are at low risk of acquiring disease, but should minimize the time spent in the cell. Those who have not received BCG or who are immunocompromised should avoid contact with the detainee wherever possible. Any staff member who is pregnant, regardless of BCG status or type of TB, should avoid contact all together.

Anyone who has had a significant exposure should report to Occupational Health or their GP if no other route exists for testing and treatment if needed. They should also be educated as to the symptoms of TB. Anyone who is likely to come into repeated contact with individuals at risk of TB should receive BCG (if they have not already done so) regardless of age, even though there is evidence to suggest that BCG administered in adult life is less effective. This does not apply to immunocompromised individuals or pregnant women. In the latter case, vaccination should preferably be deferred until after delivery. HIV positive people should never be given BCG.

Detainees with disease (whether suspected or diagnosed) who have not been treated or treatment is incomplete (i.e. less than 2 weeks) should be kept in custody for the minimum time possible. Immunocompromised individuals with TB are usually too ill to be detained, but if they are, they should be considered at greater risk of transmitting disease to staff. Any detainee with disease should be encouraged to cover their mouth and nose when coughing and sneezing.

Staff should wear gloves when in contact with the detainee and when handling clothing and bedding. Any bedding should be bagged after use and laundered or

WIT.0043.0086.0381

incinerated. The cell should be deemed out of action until it has been ventilated and professionally decontaminated, although there is no hard evidence to support that there is a risk of transmission from this route.

Severe Acute Respiratory Syndrome SARS-CoV and Middle East Respiratory Syndrome MERS-CoV

On March 142,003, the WHO issued a global warning to health authorities about a new atypical pneumonia called SARS. The earliest case was believed to have originated in the Guandong province of China on 16 November 2002. The causative agent was identified as a new Corona virus—SARS-CoV [77, 78]. By the end of June 2003, 8422 cases had been reported from 31 different countries with a total of 916 deaths. Approximately 92% of cases occurred in China (including Hong Kong, Taiwan and Macao). The case fatality rate varied from <1% in people less than 24 years old, to over 50% in persons 65 or older. On 5 July 2003, the WHO reported that the last human chain of transmission of SARS had been broken and lifted the ban from all countries. However, they warned that everyone should remain vigilant, as resurgence of SARS was still a possibility and this indeed proved the case with reports ongoing until May 2004. Since then, there have been no further reported cases. Knowledge about the epidemiology and ecology of SARS-CoV and the disease remains limited; however, the experience gained from the previous outbreak enabled the disease to be contained rapidly—reflected in the few cases reported since December. There is still no specific treatment or preventative vaccine that has been developed to date.

Another coronavirus, MERS-CoV was identified in Saudi Arabia in 2012 which causes a similar clinical picture to SARS. This zoonotic disease is acquired by humans through direct or indirect contact with dromedary camels. Since 2012 27 countries have reported cases of MERS including Algeria, Austria, Bahrain, China, Egypt, France, Germany, Italy, Jordan, Malaysia, the Netherlands, Oman, Philippines, Qatar, Saudi Arabia, Thailand, Tunisia, Turkey the UK, the USA and Yemen. Over 90% of all reported cases have been from the Kingdom of Saudi Arabia. Cases outside the Middle East have originated in travellers to that area. There was one large outbreak in the Republic of Korea with 186 cases reported Approximately 35% of patients with MERS have died but this may be an overestimate as milder cases that are not being reported are not included. As of the 3rd September 2018 2241 cases of MERS-CoV have been reported to WHO with at least 795 deaths [79].

PHE reported a laboratory confirmed case in August 2018 from a resident of the Middle East who had travelled to the UK. The last case reported from the UK was in 2013. The risk of infection to UK residents remains very low but HCPs should remain vigilant. It is important that any suspected cases are identified early and reported to local health protection teams as soon as possible.

Incubation Period and Symptoms

The incubation period for SARS is around 3–6 days (maximum 10 days), and for MERS-CoV 2–14 days with a median of 5 days.

WIT.0043.0086.0382

The following clinical case definition of SARS has been developed for public health purposes [80].

A person with a history of:

- Fever (at least 38 °C)
- And, one or more symptoms of lower respiratory tract illness (cough, difficulty in breathing, dyspnea)
- And, radiographic evidence of lung infiltrates consistent with pneumonia or Respiratory Distress Syndrome, or post mortem findings of the above with no identifiable cause
- And, no alternative diagnosis can fully explain the illness.

The clinical symptoms of MERS-CoV ranges from asymptomatic or mild respiratory symptoms to severe acute respiratory disease and death. Pneumonia is common and gastrointestinal symptoms including diarrhea have also been reported. Severe cases require hospitalization and mechanical ventilation. More severe disease occurs in older people, those who are immunosuppressed or who have chronic diseases such as cancer, renal disease, diabetes and other chronic lung diseases. The algorithm for possible cases of MERS-CoV can be found at https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/732267/Algorithm_case_v31-Aug2018.pdf.

Route of Transmission

SARS is spread by close contact with an infected individual via aerosol or infected droplets. Most cases occurred in hospital workers caring for an index case or their close family members. The virus can also be spread by hands and other objects the droplets have touched. The virus has also been shown to survive in stool for up to 4 days.

For MERS-CoV the route is thought to be from dromedary camels to humans but is not fully understood. Human to human transmission does not occur easily but clusters of cases have occurred in healthcare facilities where infection control practices have been poor. No sustained human to human transmission of MERS-CoV has been documented anywhere in the world [81].

Management in Custody

There have been no cases of SARS since 2004, but cases of MERS-CoV do continue to occur so should be borne in mind for returning travelers who present with respiratory symptoms. There is no vaccine or medicine specific for MERS-CoV so treatment is just supportive and is based on the clinical condition of the patient.

Infections Transmitted Through the Faecal-Oral Route

General Considerations

The most consistent feature of diseases transmitted through the fecal-oral route is diarrhea (see Table 10.8). Infective agents include bacteria, viruses and protozoa.

Table 10.8 Common causes of infective diarrhea

Cause	Symptoms	Incubation	Infectivity	Notes
Campylobacter	C, F, N, V, BD	1–10 days	Untreated—7 weeks	Requires antibiotics. Seek advice. Exclude from custody in acute phase
E coli 0157:H7	BD rarely WD, F is rare	3–8 days	Up to 48 h after diarrhea and vomiting stops around 7 days	Person to person spread. Can be serious with TTP HUS, dehydration, seek advice. Antibiotics not usually used as can increase risk of HUS and increase toxin production
Norwalk Virus	N, V, D, AP, F	24–72 h	Up to 48 h after diarrhea stops	Mild to moderate self-limiting
Rotavirus	F, V, WD ± AP	24–72 h	Up to 8 days but up to 30 days in immunocompromised	Symptomatic treatment. Persists in environment
Salmonella	H, AP, D, N, F ± V	6–72 h	Days to weeks	Persistent carriage can occur. Requires antibiotics. Seek advice
Shigella	DY/WD, F, N, (C, V)	12–96 h	Up to 4 weeks	Usually mild but can be severe in IC. Needs antibiotics Seek advice

AP abdominal pain, *H* headache, *BD* bloody diarrhea, *HUS* hemolytic-uremic syndrome, *C* cramps, *IC* immunocompromised, *D* diarrhea, *N* nausea, *DY* dysentery (blood and mucus), *TTP* thrombotic thrombocytopenic purpura, *F* fever, *V* vomiting, *WD* watery diarrhea

WIT.0043.0086.0383

WIT.0043.0086.0384

Since the causes are numerous, it is beyond the remit of this chapter to cover them all. It is safest to treat all diarrhea as infectious unless the detainee has a proven non-infectious cause (e.g. Crohn's disease, ulcerative colitis).

All staff should wear gloves when in contact with the detainee or handling clothing, bedding etc. and contaminated articles should be laundered or incinerated. The cell should be professionally cleaned after use paying particular attention to the toilet area.

Hepatitis A

Epidemiology and Prevalence

This viral hepatitis occurs worldwide with variable prevalence. It is highest in countries where hygiene is poor and infection occurs all year round. In temperate climates, the peak incidence is in autumn and winter, but the trend is becoming less marked.

All age groups are susceptible if they are non-immune or have not been vaccinated. In developing countries, the disease occurs in early childhood, whereas the reverse is true in countries where the standard of living is higher.

In the UK, there has been a gradual decrease in the number of reported cases from 1990 to 2000 [82, 83]. This is due in part to improved standards of living and the introduction of an effective vaccine. In 2015 there were 330 confirmed cases of hepatitis A. The highest incidence occurred in the 15–34-year-old age group [84].

In the UK between July 2016 and January 2017, 37 confirmed cases of hepatitis A were reported from eight areas in England and Northern Ireland and of those 28 were identified among MSM [85]. Since 2016, 1173 confirmed cases of hepatitis A have been reported from 15 EU countries. Most cases were reported among MSM [86]. Cases in the UK and the EU have been with identical strains prompting the European Centre for Disease Prevention and Control (ECDC) to issue a rapid risk assessment in December 2016 [86]. The outbreak emphasized the need for awareness of hepatitis A among the MSM population.

Symptoms

The clinical picture ranges from asymptomatic infection through a spectrum to fulminant hepatitis. Unlike HBV and HCV, HAV does not persist or progress to chronic liver damage. Infection in childhood is often mild or asymptomatic, but in adults tends to be more severe.

Following an incubation period of 15–50 days (mean 28 days), symptomatic infection starts with the abrupt onset of jaundice anything from 2 days to 3 weeks after the anicteric phase. It lasts for approximately the same length of time and is often accompanied by a sudden onset of fever.

WIT.0043.0086.0385

HAV infection can lead to hospital admission in all age groups, but is more likely with increasing age.

The overall mortality is less than 1%, but 15% of people will have a prolonged or relapsing illness over 6–9 months. Fulminant hepatitis occurs in <1% of people, but is more likely over the age of 65 or in those with pre-existing liver disease. In hospitalized patients, case fatality ranges from 2% in 50–59 year olds to nearly 13% in those older than 70 years [83].

Period of Infectivity

The individual is most infectious in the 2 weeks before the onset of jaundice when they are asymptomatic. This can make control of infection difficult since the disease is not recognized.

Routes of Transmission

The main route is fecal-oral through the ingestion of contaminated water and food. It can also be transmitted by close personal contact including homosexuals practicing anal intercourse and fellatio. There is a very slight risk from blood transfusions if the donor is in the acute phase of infection. It should not be considered a risk from needlestick injuries unless clinical suspicion of HAV is high.

Risk Groups

Risk groups include the homeless, MSM, PWID, travellers abroad who have not been vaccinated, patients with chronic liver disease and chronic infection with HBV and HCV, employees and residents in day-care centers and hostels, sewage workers, laboratory technicians and those handling non-human primates.

Several large outbreaks have occurred among injecting drug users—some with an epidemiological link to prisons [87, 88]. Transmission occurs during the viremia phase of the illness through sharing injecting equipment and via fecal-oral routes because of poor living conditions [89]. There have also been reports of HAV being transmitted through drugs that have been carried in the rectum. A study in Vancouver showed that 40% of injecting drug users had past infection of HAV and they also showed an increased prevalence among men who have sex with men [90].

Management in Custody

Staff with disease should report to Occupational Health and stay off work until the end of the infective period. Those in contact with disease (either through exposure at home or from an infected detainee) should receive prophylactic treatment as soon as possible (see below).

WIT.0043.0086.0386

To minimize the risk of acquiring disease in custody, staff should wear gloves when dealing with the detainee then wash their hands thoroughly. Gloves should only be disposed of in the clinical waste bags.

Detainees with disease should be kept in custody for the minimum time possible. They should only be sent to hospital if fulminant hepatitis is suspected. The cell should be quarantined after use and professionally cleaned. Any bedding or clothing should be handled with gloves and laundered or incinerated according to local policy. Detainees reporting contact with disease should be given prophylactic treatment as soon as possible (see section "Post exposure prophylaxis").

Post exposure Prophylaxis

Contacts of HAV should receive HAV vaccine (e.g. Havrix Monodose or Avaxim) if they have not been previously immunized or had disease. Human normal immunoglobulin (HNIG) 500 mg deep im in gluteal muscle should be used in the following circumstances:

- The contact is aged 60 or over and it is within 14 days of exposure
- Also for close contacts within 14 days of exposure who are HIV positive and have a CD4 count <200 cells/mm^3
- For contacts who are immunosuppressed for other reasons within 14 days of exposure.

If time allows anyone needing HNIG should be tested for IgG antibodies to hepatitis A (anti-HAV IgG) [91].

Staff at higher risk of coming in contact with HAV should consider being vaccinated prior to exposure. Two doses of vaccine given 6–12 months apart provide around 25 years of protection. There is no specific treatment for HAV except supportive measures and symptomatic treatment.

Exotica

Although the chance of encountering a tropical disease in custody is small, it is worth bearing in mind. It is not necessary for a healthcare professional to be able to diagnose the specific disease, but simply to recognize that the detainee/staff member is ill and whether or not they need to be sent to hospital. This is best achieved by knowing the right questions to ask and carry out the appropriate examination. Tables 10.9, 10.10, and 10.11 should be used as an aide memoire in order not to miss some more unusual diseases.

Illustrative Cases 1. A police officer sustained a needle stick injury whilst searching a detainee's property. The needle penetrated his gloves and drew blood. The officer reported the injury immediately to the HCP who encouraged the puncture to bleed and washed the area well with soap and water and applied a plaster.

WIT.0043.0086.0387

Table 10.9 Suspicion of exotica? History and examination aide memoire

Has the detainee travelled to Africa, South East Asia, the Indian Sub-continent, Central/South America or the Far East in the last 6–12 months
Ascertain whether they received any vaccinations prior to travel and what
Ask if they took malaria prophylaxis, what type and whether they completed the course
Ask if they swam in any stagnant lakes during the trip
If yes to any of the above, ask if they have experienced any of the following symptoms:
A fever/hot or cold flushes/shivering
Diarrhea ± abdominal cramps ± blood or slime in the stool
A rash
Persistent headaches ± light sensitivity
Nausea or vomiting
Aching muscles/joints
A persistent cough (dry or productive) lasting at least 3 weeks

Table 10.10 Examples of tropical diseases that present with a fever

Disease	Countries	Incubation	How transmitted	Management
Dengue	Caribbean and S. America, Asia, Africa	3–14 days	Mosquito—no human to human in the UK	Usually symptomatic
Ebola	Sub Saharan Africa	2–21 days	Body fluids from infected people	Isolation and hospitalisation
HFRS[a]—Hanta virus	Europe, Asia, Africa	2 days to 8 weeks	Rat, mouse and vole excreta and body fluids	Hospital
HPS[b]—Hanta virus	North and South America	2 days to 8 weeks	Rat, mouse and vole excreta and body fluids	Hospital
Lassa fever	West Africa	6–21 days	Rat urine and excreta	Isolation and Hospitalisation
Malaria	Sub Saharan Africa, some parts of Asia and South America, Vanuatu	7 days to 1 year	Mosquito—no human to human transmission in the UK	May need urgent treatment
Yellow fever	Sub Saharan Africa and South America	3–6 days	Mosquito—no human to human transmission in the UK	Often needs hospital treatment

[a]*HFRS* haemorrhagic fever with renal syndrome
[b]*HPS* hantavirus pulmonary syndrome

Details of the incident were recorded along with a medical history of the police officer and details of vaccinations received. The police officer reported that he had not had any hepatitis B vaccine. He had no underlying health concerns.

The HCP spoke with the detainee who admitted injecting drugs and to sharing needles. He last shared a needle more than 3 months ago and had no other risk fac-

WIT.0043.0086.0388

Table 10.11 Examples of tropical diseases that can present with diarrhoea

Disease	Incubation	Infectivity	Transmission route	Management
Amoebic dysentery	Days to months	Years	Oral-fecal	Anti-parasitic treatment e.g. metronidazole
Cholera	Hours to 5 days	3–5 days after recovery	Oral-fecal Vomit	Requires antibiotics
Gardia	3–25 days	Months	Oral-fecal	Anti-parasitic treatment e.g. tinidazole
Malaria	7 days to 1 year	None	None	Urgent treatment—hospital
Typhoid[a]	Up to 3 days	Days to weeks	Oral-fecal	Requires antibiotics

[a]Typhoid can also present as a fever

tors. The HCP asked if the detainee was willing to provide a sample of blood which would be tested for hepatitis B, HIV and hepatitis C. The detainee agreed and signed a consent form which was countersigned by the HCP and an independent police officer. Ten mLs of clotted blood was taken from the detainee which was given to the police officer involved who took it to the designated hospital. A 10 mL clotted sample of blood was taken at the hospital from the police officer as a baseline blood to be stored.

Testing of the detainee's blood revealed the following:

HBs Ag positive
HCV antibody positive
HIV antibody/Ag negative

Based on these findings and the unvaccinated status of the police officer—HBIG was administered into the gluteal region along with the hepatitis B vaccination in to the deltoid region. Arrangements were made to follow up the police officer to receive two further doses of hepatitis B vaccine at 4 and 8 weeks. Further screening for hepatitis C RNA at 6 and 12 weeks and for HCV antibodies at 12 and 24 weeks. A test for HBsAg would also be conducted at 24 weeks.

2. A detainee was arrested and brought into custody. Whilst filling in the risk assessment form the Custody Sergeant became aware that the detainee was on medication for pulmonary TB.

   The HCP was asked to examine the detainee and established that the diagnosis of TB had been made 3 weeks ago.

   The detainee had been prescribed isoniazid and rifampicin for 6 months with ethambutol and pyrazinide for the first 2 months. She reported that she had taken her medication every day for the last 20 days. This was evidenced by the number of tablets that had gone from the supply given. She said that she was feeling less tired and was no longer getting night sweats.

The HCP concluded that with such good compliance the detainee was unlikely to be infectious now and was therefore safe to remain in custody.

WIT.0043.0086.0389

Key Points

- The aim of adopting standard precautions with all personnel is to prevent transmission of BBVs by considering that blood and other body fluids are potentially infectious.
- The vulnerable population of patients seen in police custody are at risk of a number of infections due to general poor health, intravenous drug use, and social circumstances. There needs to a high index of suspicion and careful consideration as to whether treatment is required, including referral to hospital.

Self-Assessment Exercises

1. Place these hepatitis B markers in order of infectivity starting with the least infectious and give the % chance of acquisition of hepatitis B following a needle stick injury for each:
   HBsAg, HBeA, HBeAg, HBSA
2. When is the earliest time for detecting (a) antibodies, (b) RNA following infection with hepatitis C virus?
3. (a) What is the current recommended regime for PEP in the UK?
   (b) How long after exposure can PEP be considered?
4. When would you send a detainee or staff member with chicken pox to hospital? Give at least two examples
5. What are the main criteria for giving prophylactic antibiotics following human and other animal bites? Name the first choice of antibiotic and an alternative for people with allergies to penicillin.

Fitness to Be Interviewed and Fitness to Be Charged

11

Margaret M. Stark and Keith J. B. Rix

Learning Objectives

Explain the different types of false confessions.

Be able to describe the various conditions, both physical and mental, that might result in vulnerability.

Explain how to evaluate whether a detainee might be at risk during a police interview.

Introduction

The interview of suspects or persons of interest is an essential component of all systems of criminal investigation. Codes C of the Codes of Practice of the Police and Criminal Evidence Act 1984 (PACE) [1] and the Police and Criminal Evidence (Northern Ireland) Order 1989 (PACE(NI)O) [2] define an interview as:

> *'the questioning of a person regarding their involvement or suspected involvement in a criminal offence or offences which […] must be carried out under caution'*. (Code C 11.1A)

Section 82 (1) PACE defines a confession as including any statement wholly or partly adverse to the person who made it.

The confessions and other incriminating statements that are obtained during interviews have always played an important role in prosecutions and continue to be relied on as evidence of guilt in a substantial number of trials. For example, in England and Wales, confessions have been found to provide the single, most important piece of evidence against defendants in the Crown Court, being crucial in about 30% of cases [3]. Similarly, an influential American observational study found that interview was necessary for solving the crime in about 17% of cases [4]. Whereas in Scotland corroboration of a suspect's confession has always been required; other than in exceptional cases there is a need for two separate sources of evidence before a case comes to trial. The quest to obtain confessions from the mouths of suspects has seen a slow and uneven move away from the inquisitions aided by torture and oppression of the Middle Ages toward the doctrine that:

> *A free and voluntary confession is deserving of the highest credit, because it is presumed to flow from the strongest sense of guilt and therefore it is admitted as proof of the crime to which it refers; but a confession forced from the mind by the flattery of hope or by the torture of fear comes in so questionable a shape when it is to be considered as the evidence of guilt, that no credit ought to be given to it; and therefore it is rejected* [5].

In the years since this judgment, considerable effort has been expended on attempting to regulate the custodial interview in order to minimize the risk of false confessions while preserving the value of interrogation as a means of solving crime. In this section, we will consider the important psychological aspects of interview and confession and then discuss the role the healthcare professional (HCP) can play in ensuring that suspects are fit to be interviewed.

Police Interview Techniques

A number of American manuals detail the way in which coercive and manipulative interrogation techniques can be employed by police officers to obtain a confession [6, 7], with similar techniques being advocated by Walkley [8] in the first such manual written for British officers. The authors of these manuals propound various highly effective methods for breaking down a suspect's resistance while justifying a certain amount of pressure, deception, persuasion, and manipulation as necessary in order for the "truth" to be revealed. Walkley acknowledges that "if an interviewer wrongly assesses the truth-teller as a lie-teller he may subject that suspect to questioning of a type which induces a false confession." Generally, however, the manuals pay scant attention to the fact that, in certain circumstances, the techniques they recommend may make a suspect confess to a crime he or she did not commit and there is now a considerable body of experimental evidence that raises serious concerns about the use of such techniques [9]. Manipulative and persuasive tactics continued to be used in England and Wales, particularly in relation to more serious crimes, at least until the late 1980s and early 1990s [10–12].

Interviewers are encouraged to look for verbal clues, nonverbal clues and behavioural attitudes which indicate deception. However, the innocent as well as the

guilty may exhibit signs of nervousness. Innocent suspects may be anxious because they are erroneously being accused of being guilty, because of worries about what is going to happen to them while in custody, and possibly because of concerns that the police may discover some previous transgression. Furthermore, there are three aspects of a police interview that are likely to be as stressful to the innocent as to the guilty: the stress caused by the physical environment in the police station, the stress of being isolated from family and friends, and the stress caused by the suspect's submission to authority. All these factors can markedly impair the performance of a suspect during interview. Indeed, American research has suggested that for most suspects interviews are likely to be so stressful as to impair their judgement on such crucial matters as the exercise of legal rights [13]. Furthermore in an experimental study comparing forensic investigators and students, although the investigators were better than students in distinguishing between true and false denials, they were significantly more likely to make false positive errors suggesting a bias towards perceiving deception where there is none [14]. As observed by Vrij [15] '*once innocent suspects are mistakenly identified as guilty, they run the risk of being submitted to an interview style that is even more grilling than the interview style that guilty suspects are subjected to*.' It is little wonder that false confessions are made to the police.

False Confessions

During the last two decades of the twentieth century, the United Kingdom (UK) witnessed a number of well-publicized miscarriages of justice in which the convictions depended heavily on admissions and confessions made to the police that were subsequently shown to be untrue [16–18]. In reviewing 70 earlier wrongful imprisonments that occurred between the years 1950 and 1970, Brandon and Davies [19] found that false confessions were second only to incorrect identification evidence as the most common cause of wrongful conviction. In 1994, Justice [20] identified 89 cases in which an alleged miscarriage of justice rested on a disputed confession. There has been no comparable research this century in the UK but the number of such cases considered by the Criminal Division of the Court of Appeal of England and Wales suggests that such miscarriages of justice are now less frequent. This is probably a result of the bedding down of PACE with its Code of Practice and the increasing use of the PEACE (Planning and Preparation; Engage and Explain; Account clarification and challenge; Closure; Evaluation) model of interviewing [21] which has formed part of a national training package for police officers since 1993 along with the influential of work of forensic psychologist and former Icelandic police officer Gisli Gudjonsson [9] which has led to what has been described as improved professionalism in investigative interviewing [22].

Gudjonnson [23] has reviewed 34 cases of miscarriages of justice between 1989 and 2009 and found that in 23 cases (68%) the conviction was overturned on the basis of a psychological vulnerability identified, including borderline IQ, personality disorder, clinical depression, pathological attention seeking, abnormal traits of

WIT.0043.0086.0397

suggestibility and or compliance. In only 10 cases (29%) were there police/procedural improprieties.

However, a review of key USA studies in [24] found that the percentage of false confessions in studies of wrongful convictions ranged from 14% to 25%. Since then there has been a singularly important study [25] of DNA exoneration cases which found that 16% of those exonerated had given detailed narratives of the crime, most of them richly contaminated accounts which were '*so persuasive, detailed, and believable that judges repeatedly upheld the convictions during appeals and habeas review*'.

Therefore vigilance must remain the watchword. People are at risk of making false and misleading admissions against their own interest. We need to turn to modern psychology to obtain insights into why this happens and to learn how it can be avoided.

Why Make a False Confession?

There is no single reason why people falsely confess to crimes they have not committed. Indeed, such confessions usually result from a combination of factors unique to the individual case. Nonetheless, Kassin and Wrightsman [26] have been able to identify three distinct types of false confession, which have been developed by Gudjonsson [27] and Shepherd [28]. These categories are voluntary, accommodating-compliant, coerced-compliant, coerced-reactive and coerced-internalized.

Voluntary False Confessions

Voluntary false confessions are offered by individuals without any external pressure from the police. Commonly the individuals go voluntarily to the police to confess to a crime they may have read about in the press or seen reported on television. Often they do so out of a morbid desire for notoriety, the individual seeming to have a pathologic desire to become infamous, even at the risk of facing possible imprisonment.

Alternatively, a voluntary false confession may result from the individual's unconscious need to expiate guilt feelings through receiving punishment. The guilt may result from real or imagined past transgressions or, occasionally, may be part of the constant feeling of guilt felt by some individuals with a poor self-image and high levels of trait anxiety.

By contrast, some people making this type of confession do so because they are unable to distinguish between fact and fantasy. Such individuals are unable to differentiate between real events and events that originate in their thinking, imagination, or planning. Such a breakdown in reality monitoring is normally associated with psychotic illness, such as schizophrenia.

On occasions, people may volunteer a false confession to assist or protect the real culprit. Gudjonsson [29] highlights some evidence that confessing to crimes to protect others might be particularly common in juvenile delinquents.

Finally, Shepherd [28] identifies a subset of individuals who falsely confess to crimes to preempt further investigation of a more serious crime.

Accommodating-Compliant False Confessions

Expanding on the original three distinct categories of false confession, Shepherd [28] recognizes a group of people for whom acquiescing with the police is more important than contradicting police assertions about what happened. In such circumstances a false confession arises from a strong need for approval and to be liked. Police conduct is noncoercive, although it does involve the use of leading questions sufficiently obvious to suggest to the suspect what answers the police want to hear. People at all intellectual levels are at risk of behaving in this manner, with those who are excessively compliant being at greatest risk.

Coerced-Compliant (or Pressured-Compliant) False Confessions

Coerced-compliant false confessions are typically elicited during persuasive interrogation: the person perceives that there is some immediate instrumental gain from confessing. The suspect does not confess voluntarily but comes to give in to the demands and pressures of the interrogators. He or she is fully aware of not having committed the crime of which he is accused, and the confession is usually retracted once the immediate threat is over. The key mechanism is dysfunctional/maladaptive coping [30].

Gudjonsson [31] suggests that the four main types of perceived immediate gain are being allowed home after confessing, bringing the interview to an end, a means of coping with the demand characteristics (including the perceived pressure) of the situation, and avoidance of being locked up in police custody. Recognizing that not all police-induced false confessions are coerced [32] and that coercion can occur from other sources than the police [33] (see below), Gudjonsson [34] now suggests that the word 'coerced', which is a legal concept, should be replaced by 'pressured'.

In these circumstances the suspect may be vaguely or fully aware of the consequences of making a false self-incriminating statement, but the perceived immediate gain outweighs, in their mind, the potential long-term consequences. They may think that their innocence will be self-evident and naively believe that the truth will come out later in court, perpetuating the belief shared by many police officers and legal advisers that what happens in the police station is not really that important.

Coerced-Reactive (or Pressured-Reactive) False Confessions

Gudjonsson [34] now recognizes a type of false confession that results from pressure by persons other than police officers such as family, friends and peers. This hitherto previously neglected group of false confessors has been identified by

WIT.0043.0086.0399

McCann [33] who suggests that as this type is likely to involve a close emotional relationship between the false confessor and the coercer it should be conceptualized separately from police coerced confession. The assumption that the relationship produces an additional pressure on the coerced person receives support from research [35] which suggested an overlap in vulnerability to compliance in personal and impersonal relationships. In such cases a refusal to comply with a request from a close friend or partner may result in a fear of emotional rejection or, if it is an abusive relationship, a fear of violence.

Coerced-Internalized (Pressured-Internalized) False Confessions

Coerced-internalized false confessions occur when suspects are gradually persuaded that they have committed a crime of which they have no recollection, or when they have become so confused that they begin to mistrust their own memory ('memory distrust') and accept a false scenario suggested by the police. In order to achieve this, the investigator has to convince the suspect that (a) there is incontrovertible evidence that they committed the crime of which they are accused, even though they have no recollection of it, and (b) there is a good and valid explanation for their having no recollection of it. This type of confession can happen under two distinct conditions:

1. The suspects have no memory of the alleged offense, even whether or not they committed it. This can be as a result of amnesia such as alcohol-amnesia. In essence, the suspects have no clear recollection of what they were doing at the time the offense was committed and come to believe they must have committed the crime.
2. At the outset of the interview, the suspects have a clear recollection that they were not involved in the alleged offense. However, as a result of subtle manipulative techniques employed by the interrogator, they begin to distrust their own memory and beliefs. Interrogators attempt to undermine the suspects' confidence in their own recollection of events, which then creates sufficient self-doubt and confusion to cause them to adjust their perceptions of reality and accept the allegations put by the police. To make matters worse, the original memory contents may then be inaccessible.

In contrast to the makers of coerced-compliant false confessions, those who make coerced-internalized false confessions only come to retract when they realize, or suspect, that they are in fact innocent. These retractions can take considerable time and, on occasion, may never occur if the original memory of events becomes permanently distorted.

A key component facilitating internalization is susceptibility [36]. This can be dispositional such as naivety, low IQ, or suggestibility, or transient factors associated with custody and interrogation such as social isolation, extreme stress or sleep deprivation. Gudjonsson [37] further identifies as pre-existing vulnerabilities for

WIT.0043.0086.0400

internalized false confessions: substance misuse, memory problems and lack of confidence in memory which cause suspects to doubt their existing memory of innocence. These same vulnerabilities, which along with poor self-image/low self-esteem, suggestibility, compliance and tendency towards confabulation, can create the false belief of guilt ('plausibility acceptance') and then assist the suspect with a reconstruction based on suggested material using crime-related knowledge and imagined material and using leading and hypothetical questions.

Suggestibility, Compliance and Acquiescence

Of vital importance to an understanding of why false confessions can often prove so incriminating is an awareness of the theory of interrogative suggestibility [38, 39]. At the heart of the theory is the way leading questions can produce distorted responses from suspects because they are phrased in such a way as to suggest the expected response. Through this process people can come to accept a piece of post-event information and incorporate it into their memory, thus appearing to have "special knowledge" about the alleged offense. This special knowledge may seriously mislead the police and the courts to assume the suspect's guilt erroneously. Suggestibility has been found to be moderated by factors such as anxiety, poor memory, history of life adversity, poor self-esteem, and low intelligence [40]. These factors impair the suspect's ability to cope with the uncertainty and expectations contained within questioning.

Compliance refers to the tendency of people to obey the instructions of others when they don't really want to, either because they are overeager to please or are simply unable to resist the pressure [41]. The traits of both suggestibility and compliance have been shown to be relevant to the issue of false confessions [42].

Acquiescence is the manner by which people answer questions in the affirmative irrespective of content. Acquiescence is more highly correlated with low intelligence than suggestibility or compliance [40].

Preventing False or Otherwise Unreliable Confessions

It is a fundamental tenet of both American and English law that reliance should only be placed on confession evidence that is given freely and voluntarily. In considering the voluntary nature of a confession, several factors will need to be considered. These include the vulnerability of the accused (as a result of factors such as age, mental illness, intellectual disability, physical illness or injury, intoxication with alcohol or other substances, memory problems, suggestibility, compliance), the conditions of detention (lack of access to legal advice, failure to be given legal rights, adequate rest periods during detention, solitary confinement, lack of social support, continued interrogation over a long period of time, physical violence by the police), and the characteristics of the interrogation (pressure, manipulation, threats, physical abuse, inducements etc.).

WIT.0043.0086.0401

In America the most important legal development designed to protect the rights of suspects and deter police misconduct relates to the case of Miranda v Arizona, which was decided in 1966 [43]. The effect of this judgment was to ensure that all criminal suspects in police custody must be warned against self-incrimination and made aware of their right to remain silent and to receive legal advice. These rights have to be actively waived by the accused before interrogation can commence, and any violations of the requirements render any subsequent confession inadmissible.

In England and Wales and in Northern Ireland, statutory safeguards are provided by PACE and the PACE(NI)O respectively and their Codes of Practice [1, 2], which regulate practice in respect to a number of matters including the detention, treatment, and questioning of persons by police officers.

Specifically s 76 of PACE deals with the challenges to the admissibility of confessions in criminal proceedings. Under s 76(2) the court shall not allow a confession to be admitted if it was or may have been obtained:

(a) by oppression

(b) in consequence of anything said or done which was likely … to render unreliable any confession which might be made by him in consequence thereof.

Section 78(1) of PACE states that the court may refuse to allow confession evidence if it appears that:

> *"having regard to all the circumstances, including the circumstances in which the evidence was obtained, the admission of the evidence would have such an adverse effect on the fairness of the proceedings that the court ought not to admit it."*

The fairness of the trial proceedings in criminal cases is guaranteed by Article 6 of the European Convention on Human Rights. Confessions will generally be inadmissible if the provisions of the Codes of Practice are breached by the police [44, 45].

The role of the HCP when assessing a suspect's fitness for interview is seen as fitting into this overall legal framework. The HCP's primary concern being to recognize any characteristics that might render the individual vulnerable to providing a false or otherwise unreliable confession so that adequate safeguards can be put in place.

A Definition of Fit for Interview

Previously there was no clear definition of what precisely is meant by the term "fit to be interviewed," which has led to confusion among those doctors called on to perform these assessments [46]. To address this deficiency Norfolk [47] proposed a definition that was used as the starting point for discussion by a subgroup set up by the Home Office Working Party on Police Surgeons in the UK. That working party made an interim recommendation [48], which has now been modified and included since 2003 in the PACE Codes of Practice [42], thus providing the first Parliamentary approved definition of the term fitness for interview. The Codes of Practice state that:

A detainee may be at risk in an interview if it is considered that:

(a) Conducting the interview could significantly harm the detainee's physical or mental state.
(b) Anything the detainees say in the interview about their involvement or suspected involvement in the offence about which they are being interviewed might be considered unreliable in subsequent court proceedings because of their physical or mental state.

Thus, a suspect with known ischemic heart disease who is experiencing chest pain satisfies the criteria of (a) above and clearly needs assessment and appropriate treatment before it is safe to conduct an interrogation.

In Scotland equivalent safeguards derive from Lord Hodge's ruling in *HM Advocate v Duncan and Stewart* [2006] HCJ 06:

> '*the test is one of fairness in all the circumstances, having regard not only to the means by which the interview was conducted but also other circumstances which might place the accused in a position of such disadvantage that he could understand neither the situation he was in nor his right not to answer the questions which were put to him*.'

The concept of unreliability may be harder to evaluate and will require consideration of the various vulnerability factors associated with false confessions. In making an assessment, the Codes of Practice [49] require the HCP to consider:

1. How the detainee's physical or mental state might affect their ability to understand the nature and purpose of the interview, to comprehend what is being asked, and to appreciate the significance of any answers given and make rational decisions about whether they want to say anything;
2. The extent to which the detainee's replies may be affected by their physical or mental condition rather than representing a rational and accurate explanation of their involvement in the offense;
3. How the nature of the interview, which could include particularly probing questions, might affect the detainee.

Recognizing that '*vulnerable persons are often capable of providing reliable evidence'* but *'may, without knowing or wanting to do so, be particularly prone in certain circumstances to provide information that may be unreliable, misleading or self-incriminating'* [50, 51], the England and Wales Code C includes particular provisions relating to persons who *'may be vulnerable as a result of having a mental health condition or mental disorder'* [52]. Vulnerable applies to any person who, because of a mental health condition or mental disorder [53]:

(i) May have difficulty understanding or communicating effectively about the full implications for them of any procedures and processes connected with:
   - Their arrest and detention; or (as the case may be)

WIT.0043.0086.0403

- Their voluntary attendance at a police station or their presence elsewhere, for the purpose of a voluntary interview; and
- The exercise of their rights and entitlements.

(ii) Does not appear to understand the significance of what they are told, of questions they are asked or of their replies;

(iii) Appears to be particularly prone to:
- Becoming confused and unclear about their position;
- Providing unreliable, misleading or incriminating information without knowing or wishing to do so;
- Accepting or acting on suggestions from others without consciously knowing or wishing to do so; or
- Readily agreeing to suggestions or proposals without any protest or question.

Code C of PACE(NI)O makes similar provisions for those with 'mental disorder', as defined in s 305 of the Mental Capacity Act (Northern Ireland) 2016 as 'any disorder or disability of the mind', mental vulnerability or communication difficulties.

Mental vulnerability probably includes states of extreme emotion and distress [54]. This is of particular relevance because Gudjonsson et al. [55], in a study for the Royal Commission on Criminal Justice, found that a third of suspects were not in a normal mental state while in police custody due to extreme distress or mental disorder. This could impair their capacity for rational decision-making or coping effectively with interview and they have suggested that even detainees whose mental health or psychological problems do not amount to actual mental illness or mental disorder are potentially vulnerable to giving misleading or unreliable statements.

The Codes of Practice of PACE Code C 11.15 state that a juvenile (child under 18 years of age) or vulnerable person must not be interviewed regarding their involvement or suspected involvement in a criminal offence or offences, or asked to provide or sign a written statement under caution or record of interview in the absence of the appropriate adult unless certain circumstances prevail. An officer of the rank of superintendent or above must authorize such an exceptional interview. Code C of PACE(NI)O Codes has a similar provision (11.15, 11.18).

An appropriate adult means (Code C Annex E):

(i) a relative, guardian, or other person responsible for their care or custody;

(ii) someone experienced in dealing with vulnerable persons, but who is not:
  (a) a police officer;
  (b) employed by the police;
  (c) under the direction or control of the chief officer of the police force;
  (d) a person who provide services under contractual arrangements (but without being employed by the chief officer of the police force) to assist that force in relation to the discharge of its chief officers functions:
  (e) whether or not they are on duty at the time.

(iii) failing these some other responsible adult aged 18 or over who is other than a person described above.

The role of the appropriate adult is to safeguard the rights, entitlements and welfare of the detainee. There may be a significant problem with interviewing the mentally vulnerable without support in that any evidence obtained maybe unreliable, misleading, self-incriminating, and the vulnerable person may not be sure what is in their best interests. In the case of *R v Aspinall* [56] the failure to follow the requirements to have an appropriate adult in the interview of a mentally disordered suspect meant that, despite his apparent lucidity in interview, it was unfair to admit it in evidence.

Similar legislation to PACE regarding vulnerability is found in New South Wales, Australia. The legislation in New South Wales is arguably the most extensive, compared to other States/Territories in Australia, making special provision for a range of vulnerable persons [57].

Vulnerable persons are defined in the Law Enforcement Powers and Responsibility Regulation 2016 [58] Clause 28 as:

(a) children,
(b) persons who have impaired intellectual functioning,
(c) persons who have impaired physical functioning,
(d) persons who are Aboriginal persons or Torres Strait Islanders,
(e) persons who are of non-English speaking background,

Impaired intellectual functioning is defined in the Code of Practice for CRIME (Custody, Rights, Investigations, Management and Evidence) 2012 [59] as:

- total or partial loss of a person's mental functions
- a disorder or malfunction that results in a person learning differently from a person without the disorder or malfunction
- a disorder illness or disease that affects a person's thought processes, perception of reality emotion or judgements, or that results in disturbed behaviour

Impaired physical functioning is also defined:

- total or partial loss of the person's bodily functions or part of a person's body
- the presence in the person's body of organisms causing or capable of causing disease or illness
- the malfunction, malformation or disfigurement of part of a person's body.

When a vulnerable person is identified a 'support person' and/or 'interview friend' should be contacted to provide support.

In Ireland there is a general provision under reg 3 of the Criminal Justice Act 1984 (Treatment of Persons in Garda Síochána Stations Regulations) 1987 that members of the Garda should have regard for the special needs of any detainees who

WIT.0043.0086.0405

may be under a 'physical or mental disability' and under reg 12 there is a requirement that the interview must be conducted in 'a fair and humane manner'.

Scheme of Examination

When assessing a detainee's fitness for interview, the traditional medical model of taking a history and then conducting an examination should be employed. As always, informed consent should be obtained and detailed and contemporaneous notes should be taken. The HCP should review the risk assessment performed by the custody staff during the booking in process, and speak to the custody sergeant, and other relevant police officers as appropriate, to obtain any relevant background information relating to the arrest and whether there are any specific concerns about the detainee. There may be relevant information from friends, family, witnesses, as well as hospital letters. Previous police and/or health computerized records may be a source of information (NSPIS/NICHE/SCR, etc.). If time and circumstances permit, it may also be helpful for the HCP to speak to such relatives, friends or professionals, e.g. the general practitioner, community mental health team, community drug team.

In recent years, following on from the Bradley report [60], Criminal Justice Liaison and Diversion (CJLD) teams are increasingly found in police custody centres and the courts [61]. These services identify people who have mental health, learning disability, substance misuse, or other vulnerabilities, when they first come into contact with the criminal justice system as suspects, defendants, or offenders. They screen, assess and refer onto other services. The CJLD practitioner may be able to provide the HCP tasked with the assessment of fitness to be interviewed information about the detainee's current health condition and, if required, liaise with the detainee's mental health team for further assessment and treatment, or, where required, a formal Mental Health Act assessment.

The History

As much background information as is practicable should be obtained (as outlined above) and, when possible, an indication of how long any interview is likely to take. The demand characteristics of a long interview about a suspected murder will be much greater than a short interview about a shoplifting offense.

A general medical history should be taken with enquiry made about significant illness and any prescribed and over the counter medication. The detainee should be asked whether he or she has suffered from psychiatric illness, past or present, and specific enquiry should be made about substance misuse, both alcohol and drugs. There should be questions to assess the person's educational background, as individuals with learning difficulties can be difficult to recognize and enquiring about schooling or being in receipt of a statement of special educational needs may aid identification.

WIT.0043.0086.0406

Table 11.1 Vulnerabilities to consider in the assessment of FTI

Physical vulnerability	Mental vulnerability
Medication, e.g. concern re access/pain relief	Schizophrenia
Epilepsy: post ictal state; pre-ictal aura	Bipolar disorder
Diabetes: hypoglycemia (ideally the blood glucose should be over 6 mmol/L) [63]	Psychotic episode, e.g. drug-related
Asthma	Depressive disorder (spectrum from severe to mild)
Cardiac disease	Attention deficit hyperactivity disorder (ADHD)/Attention deficit disorder (ADD)
Cerebrovascular disease	Acquired brain injury (ABI)/Dementias
Alcohol intoxication, withdrawal, delirium tremens	Alcohol dependence, Korsakoff's syndrome, Wernicke's encephalopathy
Substance misuse/dependence including intoxication or withdrawal	Substance misuse/dependence including intoxication or withdrawal
Sleep deprivation	Intellectual disability
Injuries, e.g. head injury, fractures	Post-traumatic stress disorder (PTSD)

Make sure the detainee has not been deprived of food or sleep and enquire about significant social distractions (e.g. a single parent may make a false confession in order to obtain early release from custody and a speedy reunion with his or her child). Detainees should be asked whether they have been detained before and, if so, whether they have had unpleasant experiences while in custody in the past.

The recognition of vulnerabilities (Table 11.1) is very important in the overall assessment of fitness to be interviewed. Norfolk [62] developed the acronym 'PHIT' which refers to:

- Personality factors - suggestibility, compliance, acquiescence
- Health—mental and physical (including substance misuse)
- Interview—demands and characteristics of the interview;
- Totality of the circumstances—all other relevant circumstances of the arrest and custody

The Examination

The examination should include observations on the general appearance, physical examination as appropriate, and mental state examination. A functional assessment should be performed as to whether the detainee:

(a) is aware of the reason for arrest
(b) understands the caution and can explain it
(c) understands their legal rights
  – their right to consult privately with a solicitor and that free, independent legal advice is available ('Do you need money in order to have a solicitor

WIT.0043.0086.0407

help you at the police station?' 'If you don't want a solicitor to help you now, can you change your mind later?')
  - their right to have someone informed of their arrest
  - their right to consult the Codes of Practice
  - if applicable, their right to interpretation and translation and their right to communicate with their High Commission, Embassy or Consulate

(d) is capable of making a rational decision (able to choose between relevant courses of action) and of carrying out the chosen course of action.

Each examination needs to be tailored to the individual, but HCPs should be able to assess the vulnerabilities of the detainees, both physical and mental, they have been asked to examine and thus ensure that any necessary safeguards are put in place before the interview begins.

Documenting Fitness to Be Interviewed

At the conclusion of the assessment the HCP needs to advise:

- on the need for an appropriate adult (concept of vulnerability)
- whether reassessment of the person's fitness for interview is required at a later date
- whether a (further) specialist opinion may be required
- the risks of unreliability and attempt to quantify those risks (see below).

The importance of detailed contemporaneous clinical notes of the assessment will assist the HCP if required to provide a witness statement at a much later date and give evidence in the court proceedings, including at a *voir dire* (an inquiry conducted by the judge in the absence of the jury into the admissibility of an item of evidence e.g. a confession).

The Home Office Working Group [64] identified four categories of risk:

- Definite—unlikely to be fit for interview at any stage e.g. severe dementia
- Major risk—unfit at present. Needs re-assessment or review at a later stage to establish FTI, e.g. intoxication with alcohol and/or drugs
- Some risk—precautions advised e.g. presence of AA or referral for other medical or psychiatric advice e.g. schizophrenia, depression, mild intellectual disability
- No discernible risk

If, for example, a detainee with intellectual disability is to be interviewed it will be appropriate to advise the police to keep language simple, or where an individual has a mental illness advise the appropriate adult, to be ready to intervene if particular symptoms and sings of mental illness occur such as delusional material begins to be introduced [65].

WIT.0043.0086.0408

Alcohol and Fitness for Interview

It is generally accepted that severe alcohol intoxication renders a suspect unfit to be interviewed. There is much less agreement, however, when it comes to deciding when somebody with mild or moderate intoxication should be considered fit to interview [46, 66]. The customary view that intellectual processes are impaired at lower blood alcohol levels than sensory or motor processes has been challenged. Indeed, the very opposite has been shown, with intellectual processes appearing to be more resistant to alcohol than sensory and motor skills [67]. Nonetheless, the effect alcohol can have on short-term memory should be borne in mind when advising the police on fitness. Research suggests that moderate quantities of alcohol impair the process of forming new memories [68]. Deterioration in performance of a task assessing short-term memory occurred at blood alcohol levels of 70 mg/100 mL in one study [69], and a significant impairment of eyewitness memory has been demonstrated at average blood alcohol levels of 100 mg/100 mL [70]. When suspects mistrust their own memory of events, they are at increased risk of providing coerced-internalized false confessions [71].

The ultimate decision regarding whether a suspect who has been drinking is fit for interview is best decided on the medical and functional assessment performed by the HCP rather than on arbitrarily defined "safe" blood alcohol levels [72].

Alcohol withdrawal states and the complications of alcohol withdrawal can impair cognitive functioning and affect both a suspect's ability to cope with interrogative pressure and the ability to provide reliable testimony. Even the after effects of alcohol, or "hangover," have been shown to impair critical task performance, such as aircraft operation, and can impair judgment [73]. Research evidence has also suggested that alcohol withdrawal can increase a suspect's suggestibility, although it is not totally clear whether this is a direct result of the alcohol withdrawal or a secondary effect of its treatment [74].

Illustrative Case *A 37 year old male had been arrested on suspicion of criminal damage of a motor vehicle. The police had performed a risk assessment and established that the detainee was under the influence of alcohol and there was a query that he had received brain damage a couple of months prior to this arrest. The detainee had been seen by a colleague after arrest who had concluded that the detainee was intoxicated with alcohol. The HCP was now asked to assess whether the detainee required an appropriate adult.*

The detainee gave a history of drinking alcohol daily (strong cider 8.4%). He drank alcohol on wakening otherwise he was tremulous and unable to get up. He had been drinking at this level for five years. He said he had been assaulted two months previously and this had resulted in a skull fracture requiring an operation at the local hospital. He confirmed that he had a problem with his memory since the assault.

The detainee was aware of the reason for his arrest but couldn't remember whether he had ever been arrested before. He was calm, cooperative, alert and orientated in time, place and person, and the mental state examination was entirely

WIT.0043.0086.0409

normal. He was tremulous, sweating with a blood pressure of 145/95 and pulse 98 beats per minute. The HCP concluded that there was evidence of alcohol withdrawal and provided treatment (a long acting benzodiazepine diazepam 10 mg). The HCP advised the police that in view of the history of an acquired brain injury and severe alcohol dependence the detainee would require the presence of an appropriate adult.

Substance Misuse and Fitness for Interview

A substance misuser may be rendered unfit for interview by virtue of either intoxication or withdrawal. Generally speaking, intoxication is easy to recognize, and the police will usually wait until the intoxication has cleared before starting their questioning. However, problems may be encountered with hallucinogenic substances. For example, the mental state may fluctuate in the recovery stages of an LSD experience and some of the novel psychoactive substances with hallucinogenic properties e.g. tryptamines and phenethylamines, which may not be immediately obvious to the interviewer [75].

Withdrawal states can pose a bigger problem for the doctor assessing fitness for interview. Although most confessions made in these circumstances are reliable [76], it should be recognized that the person suffering from drug withdrawal may be particularly vulnerable to providing a false confession. Such persons may believe that compliance will result in early release and that the risks entailed in providing a false confession may seem worthwhile in the presence of an overwhelming desire to reestablish access to their supply of drugs [32].

Although symptoms of mild withdrawal from opiates, for example, is considered unlikely to be a barrier to interview [46, 75], the physical and mental distress occasioned by established withdrawal may seriously impair a suspect's fitness to undergo the somewhat threatening and difficult experience of police interrogation.

When faced with a suspect suffering from severe withdrawal, the HCP should consider advising that the interview be deferred until such time as the withdrawal has subsided or been adequately treated. If the HCP decides to treat the withdrawal state, consideration should be given to the risk that the therapeutic intervention may in itself have a bearing on fitness to interview. Arranging for therapy that the suspect has been receiving in the community to be continued in police custody is unlikely to influence fitness for interview [75, 77, 78]. However, when substitution therapy is initiated in custody, or when symptomatic treatment alone is provided, the HCP may well need to assess the impact of the treatment before an interview takes place.

The Court of Appeal (Criminal Division) in *R v Crampton* (1991) 92 Cr App R 369 [79], has ruled that the mere fact that an addict is withdrawing and might have a motive for confession does not necessarily make the confession unreliable. Whether an addict is fit to be interviewed in the sense that his or her answers can be relied on as being true is a matter for those present at the time. It is therefore essential that the HCP performs a comprehensive assessment as the evidence he/she provides could be pivotal in the case.

The Impact of Psychiatric Illnesses and Personality Disorders

There has been a considerable amount of research into the manner in which certain functional psychiatric illnesses can affect the reliability of testimony [80, 81]. Thus anxiety has been shown to increase a suspect's suggestibility [82] and depression can lead to feelings of guilt and poor self-esteem that render a suspect vulnerable to providing a false confession [83]. It has been accepted that personality disorder might render a confession unreliable in *R v O'Brien* [84] and evidence of possible inaccurate elaboration on events without understanding the implications of doing so was the basis of a successful appeal against conviction for robbery in the case of a prostitute with a severe personality disorder *R v Walker* [85]. Psychiatric illness may also render a person unfit for interview by virtue of its effect on cognitive processes or because of associated thought disorder [66, 86]. However, careful questioning that avoids the use of leading questions and coercive pressures can often elicit reliable testimony. The fact that a suspect suffers from an illness such as schizophrenia does not necessarily mean that he or she is unfit for interview [87]; such an opinion would depend on the likely demand characteristics of the interview and the functional assessment by the doctor. This is reflected in Annex G of Code C of PACE and the PACE(NI)O:

> '*It is essential healthcare professionals who are consulted consider the functional ability of the detainee rather than simply relying on a medical diagnosis, e.g. it is possible for a person with severe mental illness to be fit for interview.*'

Intellectual Disabilities

Gudjonsson [88] has observed that a common theme across real-life studies is that many of the exonerated people who falsely confessed had intellectual disabilities. The police and HCPs rarely have difficulty recognizing moderate or severe learning difficulties, but borderline or low-normal intelligence may not be obvious even to trained observers [89–91]. The identification of those with ID on arrest is important to ensure that they receive the support they need and access to the appropriate services to help them understand what is happening as they go through the CJS [92]. The FFLM recommends use of a short questionnaire to ascertain the presence of an ID [93]. Detainees with ID will be particularly vulnerable and are likely to believe that they do not need legal advice, will be allowed home after confessing and will be believed if they retract a false confession [94]. Such individuals may have difficulties in understanding the caution, understanding and exercising their legal rights, making informed decisions and in communicating with police officers. They are also more likely to be suggestible and acquiescent [95].

A recent case of *Miller v DPP* [96] has confirmed how important the role of the AA is in supporting an individual throughout the custodial process. In this case the detainee had been arrested for failing to provide a specimen of blood in breach of s 7 of the Road Traffic Act 1988. The detainee was known to suffer from autism and intellectual disability and on appeal the court stated that there was a very real

WIT.0043.0086.0411

possibility that the presence of an appropriate adult would have calmed the detainee and led him to behave differently and make different choices from those he in fact made. An AA must be present so that the suspect can understand the gravity of his decision not to provide a specimen.

Neurodevelopmental Disorders

Gudjonsson [97], summarizing the results of four studies, has suggested that persons who are symptomatic for attention deficit hyperactivity disorder (ADHD) are two to three times more likely than their 'peers' to make false confessions during police questioning.

Detainees with autistic spectrum disorders (ASD) are also at risk. In *L & R v R* [2011] EWCA Crim 649 [98] the Court of Appeal ruled that an interview with L, conducted in the absence of an appropriate adult and a solicitor, should be excluded as there was evidence that L, who showed signs of ASD, was '*suggestible particularly when under pressure and when required to respond to complex statements or questions'* and was at risk of giving erroneous answers in response to a confrontational style of questioning.

The Effect of Physical Illnesses on Fitness for Interview

The presence of any physical illness renders an individual more vulnerable when faced with a stressful situation such as a custodial interrogation. Features such as anxiety or depression will affect a person's ability to function during the police interview, and physical illness, especially if severe, is as likely to cause anxiety and depression as any other form of stress [99]. The severity of the emotional response will depend on the nature of the illness itself, the personality of the individual and social circumstances. Suspects who are already coping with physical illness are more likely to focus on the short-term consequences of their behavior than the long-term ones, thus increasing the risk that they might provide a false confession.

As the impact of physical illness on a person's coping strategy is not disease specific, depending more on the actual or perceived severity of the illness rather than the nature of the illness itself, the actual diagnosis is unimportant. By contrast, there are many physical illnesses in which characteristic disturbances in cognitive functioning have been recognized [100]. With these illnesses, the nature and degree of the mental disturbance produced depends entirely on the diagnosis of the underlying condition. The more common of the conditions encountered in custody are discussed below.

Epilepsy

It is now clear, after long historical dispute, that a predisposition to epileptic fits does not mean per se that there will be associated intellectual impairment, personality disorder, or mental illness. Most epileptic patients remain mentally normal,

WIT.0043.0086.0412

although this does depend on the presence, site, and extent of any brain damage underlying the epilepsy [101].

However, people with epilepsy without significant brain damage do, nonetheless, remain prone to cognitive impairment, particularly memory impairment, as a result of their epilepsy and its treatment. The potential impact of this cognitive impairment has to be considered when assessing fitness for interview in a suspect with epilepsy.

For example, problems with concentration, memory, and intellectual functioning can be seen when anticonvulsant drugs are administered in toxic doses or unsuitable combinations [102]. Suspicion should be raised when a suspect complains of mental lethargy or appears to be performing below expected levels, symptoms particularly associated with toxicity.

Further problems with the reliability of testimony from suspects with epilepsy may be related to their personality. Patients with epilepsy are often overprotected in childhood by concerned parents and, later in life, can be exposed to profound social and occupational discrimination [103]. All these factors can lead to personality problems, which include feelings of insecurity, low self-esteem, and dependency. Individuals with these personality traits are likely to be highly suggestible and may strive to please interviewing officers by giving answers that seem plausible and consistent with the external cues provided, even though the responses are known to be untrue.

The neurophysiologic consequences of an epileptic fit can in themselves seriously distort an individual's perception of events occurring around the time of the fit, thus rendering any subsequent account of that event potentially unreliable. Complex disturbances of thinking, memory, or awareness may feature as part of an aura preceding the actual seizure. These may include distortion of time sense, mental confusion, or feelings of depersonalization or déjà vu. The fit may also be ushered in by distorted perceptions or actual hallucinations of sight, hearing, taste, or smell. When the ensuing fit is mild or abortive, the connection between these reported experiences and their epileptic causation may be missed [103].

In March 2017 the classification system for seizures was revised [104] with a new nomenclature based on where seizures begin in the brain; the level of awareness during the seizure; and other features of seizure.

Cognitive disturbances can follow in the wake of seizures, with clouding of consciousness and disorientation lasting for a few minutes or up to an hour or more, so that recollection for events occurring during the postictal period may also be unreliable [101].

Head Injury

Head injuries may occur in a number of circumstances involving possible criminal offenses such as road traffic collisions and assaults; therefore, it is not uncommon to encounter head-injured detainees in police custody. The potential for the head injury to affect the person's ability to recall the details of the accident or assault can assume considerable importance.

WIT.0043.0086.0413

Memory loss for events occurring around the time of the injury is likely to occur whenever there has been diffuse brain damage of a degree sufficient to cause concussion. In most cases loss of consciousness will accompany the head injury, but this is not invariable, and it is possible for patients to display both retrograde and post-traumatic amnesia without losing consciousness [100].

Retrograde amnesia refers to the loss of memory for events that immediately precede the head injury. Individuals can often indicate with fair precision the last event that they can clearly recollect. In road traffic collisions the journey may be recalled up to a specific point, which allows an estimate of the extent of the pre-traumatic gap to be made. Such amnesia is usually short in duration and can usually be counted in minutes or hours rather than days or weeks. Indeed, when the retrograde amnesia lasts for a long time the explanation is often due to hysteria.

Retrograde amnesia may render a suspect unfit for interview immediately after the head injury, but the HCP should be aware that the extent of the amnesia can change with time. At first it may be very long, but it can then shrink over the next days and weeks, eventually ending up as a matter of minutes only. Recovery from retrograde amnesia tends to occur in chronological order, with items in the distant past recovering first.

By contrast, post-traumatic amnesia refers to the period from the moment of the injury until normal continuous memory returns, the length of the amnesia providing a good index, albeit in retrospect, of the severity of the brain damage [105]. It should be emphasized that the amnesia only ends when the person becomes able to give a clear and consecutive account of what is happening around him or her. Sometimes "islands of memory" will be exhibited, but these should not be taken as indicating the end of the amnesia. There is a similar danger in underestimating the duration of post-traumatic amnesia in those suspects who, although aware of things going on around them, are unable to recall these events at a later date [100].

A variety of behaviors may be exhibited during the period of post-traumatic amnesia, ranging from apparent normality to obvious confusion. In general, however, behavior is unremarkable, and the HCP may be easily misled into believing that there is nothing amiss. The individuals themselves are usually unaware of the abnormal memory at the time and can give superficial or made-up explanations for any defects that are discovered. Occasionally these false memories can appear most convincing [106].

Migraine

Migraine is a common and sometimes incapacitating disorder, affecting approximately 20% of women and 15% of men at some time in their lives [107]. Some degree of mental change is almost universal during attacks. Anxiety and irritability are common early in the attack and are often followed by drowsiness and lethargy. Cognitive impairment may occur. Cerebration is often slowed with poor concentration, and there may be marked impairment of memory [100].

WIT.0043.0086.0414

Detainees who claim that they suffered an attack of migraine at or around the time of the alleged offense should be questioned closely about any cognitive impairment during previous attacks. However, it should be recognized that the pattern of any such impairment can change from attack to attack in the same person.

Hypothyroidism

A detainee who is being adequately treated for hypothyroidism poses no particular problem for the HCP assessing fitness for interview. However, an individual with undiagnosed or undertreated hypothyroidism may exhibit mental manifestations that are as important as the physical. The typical picture is of mental lethargy, general dulling of the personality, and slowing of all cognitive functions. In particular, the hypothyroid patient shows deficits in memory, abstraction, conceptual organization, and mathematical ability [108].

Diabetes Mellitus

Although confusion is a prominent feature in patients who are slipping into hyperglycemic coma, this condition is rarely seen in police custody. Questions relating to fitness for interview and the potential reliability of a detainee's confession are more likely to involve those with hypoglycemia.

Episodes of hypoglycemia are associated with irritability, anxiety, and panic in the early stages. As the episode develops, the individual becomes disinhibited and may exhibit childish or aggressive behavior that often mimics drunkenness. Disorientation and mental confusion are common and, in severe cases, the person may pass into a coma. Anybody suffering from hypoglycemia will prove to be a poor witness to events that occur during the episode. Most will have complete amnesia for the content of the attack and occasionally for an additional period before the attack occurred when their behavior will have appeared to be normal [109]. The HCP should take a clear history of any hypoglycemic episodes that may have occurred prior to arrest and should consider checking the blood glucose of any diabetic about to be interviewed by the police. The manifestations of hypoglycemia with subsequent impaired intellectual function are extremely variable, and it has been recommended that the blood sugar should be kept at 6 mmol/L or more if a diabetic person is to give a statement or be interviewed [63].

Dementia

It is estimated that there are 850,000 people in the UK with dementia with the main sub-types Alzheimer's disease, vascular dementia, mixtures of these two pathologies ('mixed dementia') and rarer types such as Lewy body dementia, dementia in Parkinson's disease and fronto-temporal dementia [110].

However, in many of these patients the dementia is not recognized until there is some form of crisis in their lives. Such a crisis may be precipitated by sudden illness, bereavement, or police arrest. Individuals seem able to develop strategies to cope with their daily tasks and thus appear to function normally until the crisis disrupts the status quo and exposes the degree of their dementia [111].

Although there are many different causes of dementia, the clinical picture remains broadly similar, with any variation depending mainly on the age of onset of the illness, premorbid personality, and intelligence. In the custodial situation the doctor is likely to encounter only those at an early stage of the disease. This is characterized by impaired memory, loss of the sense of time, and spatial disorientation, all of which can distort a suspect's recollection of events. This distortion may be compounded by the lack of judgment that is frequently displayed by those with dementia and that can cause the suspect to misjudge the importance of providing reliable testimony [100].

Therefore it is important that the HCP be aware of the possibility that an elderly suspect may be suffering from dementia, even when there are reports of apparently normal social functioning prior to arrest. In such circumstances recognition of the dementia can be facilitated by using a standard test of cognitive function, such as the Abbreviated Mental Test Score (AMTS) [112], the Six-Item Cognitive Impairment Test [113] (6CIT http://6cit.co.uk/test/) or the Mini-Mental State Examination Score [114].

Illustrative Case *An 80 year old man was arrested for shoplifting. The police performed a routine risk assessment on his arrival at the police station and found that he appeared to be 'confused'. The HCP was called to assess the detainee for fitness to be detained and fitness to be interviewed. The HCP concluded, after performing a comprehensive assessment, including a Mini-Mental State Examination, that the detainee had dementia. The HCP advised the police that the detainee was not fit to be interviewed, and was unlikely to be fit for interview at any stage due to the diagnosis of dementia. There was a definite risk that anything the detainee said in the interview might be considered unreliable in subsequent court proceedings. Furthermore the detainee's condition was unlikely to improve. Referral to the adult safeguarding team was recommended having regard to the detainee's vulnerability. The police were advised to inform the CPS that prosecution in this case would probably not be in the public interest.*

Fitness to Be Charged

A person will be fit to be charged if he/she is capable of:

- understanding the meaning of the written notice detailing the particulars of the offence (which should be stated in simple terms as well as following the precise wording of the offence in law); and
- understanding the meaning of the statutory warning that precedes the details of the charge.

WIT.0043.0086.0416

Fitness to be charged is not the same as fitness to be interviewed, as those vulnerabilities that render an individual more likely to give a false confession to the police are not relevant when considering fitness for charge. If a suspect is fit to be interviewed then he/she will also be fit to be charged unless there is any material change in their condition. Children and the mentally vulnerable should have the appropriate adult present when they are charged.

Conclusions

The Innocence Project [115] found that in about 25% of DNA exoneration cases innocent defendants made a false confession or incriminating statement. The importance of the electronic recording of all interviews has been highlighted. Currently in the US nearly half the states have a requirement for audio recording of all interviews. This occurs routinely in England and Wales. In New South Wales interviews are video and audio recorded. Whilst this makes it easier to assess the interview process, video and audio recording interviews does not necessarily ensure that false confessions do not occur.

It is essential that HCPs working in the field of general forensic medicine have the necessary competencies to be able to adequately assess a suspect with regard to fitness to be interviewed. Forensic physicians with sufficient experience of, and relevant qualifications in general forensic medicine, as well as forensic psychiatrists, may also assist in potential appeals where it is suspected that a conviction has resulted from a false or unreliable confession which should have been ruled inadmissible at trial [116].

Key Points

- A comprehensive assessment by the HCP who has the appropriate competencies (knowledge, skills, and experience) is required to assess a suspect with regard to fitness to be interviewed by the police.
- The HCP's primary concern is to recognize any characteristics that might render the individual vulnerable to providing a false or otherwise unreliable confession so that adequate safeguards can be put in place.

Self-Assessment Exercises

1. Describe the five types of false confessions.
2. What is the role of an appropriate adult?
3 Outline a scheme to recognize vulnerabilities in the assessment of fitness to be interviewed?

Acknowledgment With acknowledgement to the previous co-author Dr. Guy Norfolk who was not involved in this edition.

Substance Misuse

12

Margaret M. Stark

Learning Objectives

To demonstrate the ability to take a detailed substance use history.
To identify the symptoms and signs of alcohol withdrawal.
To describe the clinical effects of commonly used illicit drugs.
To manage the treatment of a detainee dependent on opiates.

Introduction

There are a significant number of individuals passing through the criminal justice system with substance misuse problems and it is essential that healthcare professionals (HCPs) working in the field of clinical forensic medicine are aware of the current drug trends in their area and have been trained to a standard to practice competently in this field [1]. In England for example, The National Drug Treatment Monitoring System (NDTMS) [2] consistently reports that approximately a quarter of all referrals into treatment are generated via criminal justice sources.

Statistics

Different jurisdictions collect information from different sources in an attempt to establish patterns of drug use, and the harm that results. The statistics quoted below are not directly comparable, but give an indication of drug use within a particular country.

WIT.0043.0086.0423

Statistics from the Crime Survey England and Wales 2017/2018 [3] reveal that around 1 in 11 (9.0%) adults, aged 16–59, had taken a drug in the last year; with 1 in 29 (3.5%) this was a Class A drug (in the last year). This has increased over the past decade. Furthermore class A drug use among 16–24 year olds has been increasing since 2011/2012 mainly driven by an increase in powder cocaine and ecstasy use. Figures from the National Survey on Drug Use and Health (NSDUH) in the US show that in 2016, 28.6 million people aged 12 or older used an illicit drug in the past 30 days, which corresponds to about 1 in 10 Americans overall (10.6%), but ranges as high as 1 in 4 for young adults aged 18–25 [4]. The commonest illicit drug used was cannabis, followed by prescription opioids. The NSDUH statistics also indicate that in 2016, over the past year new cocaine users rose 13.6%, from 968,000 in 2015 to 1.1 million in 2016; and in relation to heroin there was 14.5% increase in new users from 828,000 in 2015 to 948,000 in 2016.

The National Drug and Alcohol Research Centre based in Sydney, Australia, runs the Drug Trends Program which identifies emerging problems in substance use in Australia triangulating data from various sources (https://ndarc.med.unsw.edu.au/program/drug-trends). Reviewing the most recent figures (2018) from the Illicit Drug Reporting System (IDRS) [5] two in five participants (41%) reported that their drug of choice was heroin, although methamphetamine remained the drug injected most often in the past month (44%). Weekly or more frequent use of crystal methamphetamine increased in 2018 (47%), continuing an upward trend that has been observed from 2010 onwards. Cannabis use remains stable, with nearly half of consumers (45%) reported using cannabis daily, and recent use of cocaine, and frequency of use, generally decreasing amongst the national sample since the beginning of monitoring (14% in 2018).

Local knowledge is key. Tramadol is a widely prescribed analgesic of the 'synthetic opiate' class. It has become a highly abused drug, causing more deaths in Northern Ireland in 2015 than any other drug [6].

Purity of illicit substances will vary between countries and from year to year; this may be reflected in the drug history obtained, with increasing amounts ingested as drug purity diminishes, or potential complications from overdose as the purity has increased beyond an individual's tolerance level. For example a spate of deaths occurred in England in 2017 related to the presence of carfentanyl in heroin [7].

In England and Wales the average purity of powder cocaine at user-level has increased over the last 3 years, from 36% in 2014 to a record high of 54% in 2016; purity of crack cocaine has also risen from a record low of 26% in 2011 to a record high of 71% in 2016; and heroin purity reducing from 35% in 2010 to a low of 18% in 2011 (secondary to reduced supply following on the heroin drought) to 43% 2016 [7]. In the US the Drug Enforcement Administration (DEA) collates information from a variety of sources on drug purchases submitted as evidence to DEA laboratories for analysis [8]. During the period 2012–2016 cocaine purity increased from 49.1% to 62%; heroin from 29.8% to 32.3%; and methamphetamine purity from 87.9% to 94%.

Similar statistics regarding purity are collated in Australia with the annual median purity varying between states and territories:

WIT.0043.0086.0424

- amphetamine ranged from 1.5% in Queensland to 6.2% in New South Wales
- methylamphetamine ranged from 73.3% in Queensland to 82.0% in Victoria
- phenethylamines ranged from 1.8% in South Australia to 52.5% in New South Wales
- heroin ranged from 17.0% in Victoria to 71.0% in Western Australia
- cocaine ranged from 33.2% in Queensland to 60.5% in Western Australia [9].

There are now well established global surveys to determine trends in drug use. The World Drug Report [10] in 2019 reporting that the severity and complexity of drug use is increasing with 35 million people worldwide suffering from drug use disorders while only 1 in 7 people receive treatment. The Global Drug Survey (https://www.globaldrugsurvey.com/) is typically completed by young, mainly recreational drug users, revealing that the most popular drug used in this selected survey group is cannabis, followed by ecstasy. Data on the drug situation in Europe is collected annually from member States and includes the prevalence of drug use with information on seizures, price, potency and purity of individual drugs [11].

Wastewater analysis is a relatively new scientific method to estimate the quantity of drugs consumed by a community by measuring the level of illicit drugs and their metabolites excreted in urine [12]. There is a Europe-wide network (Sewage analysis CORe group (SCORE)) that coordinates research. A distinct geographical and temporal pattern of drug use across European cities has been found [13]. Benzoylecgonine (BE) has been found in wastewater at higher levels in western and southern European cities, especially Belgium, Netherlands, and UK compared to eastern European cities; amphetamine levels were at the highest in northern and east European cities. Interestingly and perhaps not surprisingly, high levels of amphetamine, BE and MDMA have been found in wastewater during the weekend than during weekdays. Drug testing at festivals has been carried out in an attempt to reduce drug-related harm [14].

Drug related deaths are increasing in the UK with the largest number of deaths associated with heroin, and the proportion of deaths involving cocaine also continuing to rise [7]. Deaths involving Novel Psychoactive Substances (NPS) have increased since 2010 in England, Wales and Scotland. The nature of the NPS involved in deaths differs between the two countries with cathinones (mainly mephedrone) responsible for the largest proportion of NPS deaths in England and Wales since they were first recorded in 2010, whereas benzodiazepine-type substances (in particular etizolam) were implicated in 98% of deaths involving NPS in Scotland in 2016 [7]. Hospital admissions related to drugs also provide evidence. Over the past 20 years, there was a fourfold increase in the rate of drug-related general acute hospital stays in Scotland (from 51 to 199 stays per 100,000 population), with a sharper increase observed in recent years [15]. There is significant global burden of disease from both alcohol and drug use [16]. In the forensic environment deaths in custody often involve drugs and alcohol (see Chap. 13).

WIT.0043.0086.0425

Drug Facilitated Crime (DFC) and Drug Facilitated Sexual Assault (DFSA)

The UK Government published a Serious Violence Strategy in 2018 stating that drugs have been an important driver of the increase in serious violence in England and Wales since 2014 [17]. The report linked drugs to violence directly via their psychoactive effects, and indirectly by fueling crime, such as robberies to service drug dependence, or through violent competition between drug dealers. It further concluded that crack cocaine markets are linked to serious violence and there has been a rise in use in England. The increase has been explained by a number of factors: aggressive marketing by the drug dealers, easy accessibility to the drug, affordability, an increase in county lines drug dealing activity, a reduction of police focus on drugs and less stigma with crack cocaine use [18]. There has also been a global increase in the production of cocaine [19].

For a HCP working in general forensic medicine or in sexual offence medicine consideration should always be given to whether drugs have been used, not only to assess the condition of the complainant or suspect at the time of the examination, but also whether there is any indication that drugs have been administered and effected the situation.

Drug facilitated crime (DFC) is any crime in the course of which the victim is administered a drug, or other incapacitating substance, in order to affect control over their actions, decision making, or mental or physical capabilities [20]. This may occur in a variety of circumstances, including cases of drug facilitated assault (DFSA).

Two forms of DFSA have been recognized [21]. Proactive DFSA involves the covert or forcible administration of an incapacitating or disinhibiting substance, by an assailant, for the purpose of sexual assault. Opportunistic DFSA involves sexual activity, by an assailant, with a victim who is profoundly intoxicated by his or her own actions to the point of near or actual unconsciousness, and thus lacks the capacity to consent.

Where DFC/DFSA is suspected samples of urine and blood need to be taken as soon as possible (see Chap. 3). Many jurisdictions use an Early Evidence Kit (EEK) that includes the taking of a urine sample. This can be facilitated by law enforcement/emergency department personnel/other first responders before the forensic HCP arrives to undertake a full forensic assessment. EEKs should be widely available as delay in obtaining samples will result in the metabolism of shorter acting drugs so that they are no longer reliably detected in blood and urine [22].

Timescales for the collection of forensic samples should be based on evidence including statistical feedback from the local laboratory. Currently blood samples are recommended within 24–72 h and urine up to 5 days [23–25]. In cases of DFC/DFSA there is often a delay so hair samples may provide evidence of drug use some time after an incident [23], including single dose exposure [26]. However it should be remembered that drugs and their metabolites found in hair may arise not only from deliberate drug administration and other factors may affect the interpretation of results [27].

WIT.0043.0086.0426

Alcohol is by far the commonest drug to be implicated in DFSA but polydrug use is common and this maybe because of voluntary ingestion or be covertly administered [28, 29]. Cannabinoids and ethanol, and benzodiazepine and alcohol, appear to be common combinations [20, 30]. Interpretation of drug and/or alcohol levels will be depend on may factors but the HCP should ensure that they take a detailed history of any substances misused, as outlined in this chapter below. Back calculations for alcohol from the complainant's blood alcohol concentration (BAC) from the time of sampling to the time of the alleged offence can be made. This is not recommended on urine [31]. The urine alcohol concentration (UAC)/BAC ratio is highly variable depending on many factors including time of the last bladder emptying before providing the urine sample for toxicological analysis [32].

General Principles [33]

History and Examination

A detailed history of recent drug use, including alcohol, needs to be obtained to establish whether the individual is a currently dependent or a recreational user (Table 12.1). Street names of substances will vary from country to country, within regions in the same country, with the cultural background of the user, and over time. The examination should look for signs of intoxication, withdrawal, or previous drug use (Table 12.2). Baseline parameters are useful for re-examination if the detainee is kept in custody. The method of administration of a drug may include enteral, parenteral, topical, and by inhalation and the speed at which the peak plasma levels of a drug are reached depends on the route of administration [34]. Those that are rapidly released have a greater abuse potential.

In recent years more research has been undertaken into the health needs of those detained by the police and this shows that in this population [35–37] mental health problems, including substance use disorders, and physical ailments, are highly prevalent, often requiring emergency referral (see Chap. 9). Many detainees are homeless and this is associated with multiple complex needs [38]. As well as taking a comprehensive substance use history it is essential that the HCP take a full medical history including [39]:

Table 12.1 Substance misuse history

Type of substance used
Period of substance use
Quantity taken per day, on an average/typical day
Amount spent on substances per day
Frequency of use
Routes of administration (noting any sites of injection)
Amount used in the past 24–48 h
The time of the last dose(s)
Currently prescribed drugs
Experience of withdrawal

Romberg's
Mental state examination (MSE)
Use of withdrawal sales CIWA-Ar & COWS

- presenting symptoms of a physical or mental health problem
- complaint of recent injuries, including use of force during arrest
- past medical history including operations, injuries, (especially significant head injuries) and periods in hospital
- past psychiatric history including periods in hospital, contact with mental health team
- for women, relevant contraception history, cervical screening, menstrual and pregnancy history
- consideration of sexual health and history of sexually transmitted infections (including any partners with HIV or hepatitis B, C)
- oral health problems
- current prescribed medication

The use of an onsite drug testing kit in police stations may be of assistance [33]; however, these tests are qualitative rather than quantitative indicating that a substance has been used rather than how much has been taken, or whether the detainee is dependent, so care is needed in the overall interpretation. Urine tests have been used as part of the clinical management in police custody settings [40] and the results of oral fluid sampling undertaken by police may be available.

WIT.0043.0086.0428

Pregnant detainees need very careful assessment and management as sudden cessation of opioid use in a pregnant woman with dependence may be life-threatening for the fetus. Special care should be taken to ensure that a pregnant, opiate-dependent woman's medication is continued while she is in custody. There should be a low threshold for referral for hospital assessment, especially in the third trimester. It is important to consider whether or not a female detainee is pregnant before initiating treatment. Detailed guidance has been issued for the management of pregnant detainees in police custody [33].

Medical Complications of Substance Misuse

Medical complications of substance misuse may give an indication of a problem in the absence of acute symptoms or signs of intoxication or withdrawal [41]. Intravenous injection may result in superficial thrombophlebitis, deep vein thrombosis and pulmonary embolus, and chronic complications of limb swelling and venous ulcers. If injection occurs accidentally into an artery vascular spasm may result in ischemia which, if prolonged, can lead to gangrene and amputation.

Cellulitis and abscesses may be seen around injection sites, and deep abscesses may extend into joints, producing septic arthritis. Self-neglect, malnutrition, and dental decay may occur, as may infectious diseases such as hepatitis B, C, HIV, and the acquired immunodeficiency syndrome (AIDS). An outbreak of anthrax among injecting heroin users in 2009–2010 from contaminated heroin, occurred due a single novel strain of anthrax not previously seen in the UK, but found to related to anthrax strains previously identified in goats in Turkey [42].

Skin manifestations of drug use [43] may be seen more commonly in opiate rather than stimulant users, even though stimulant users inject more frequently. This is partly because stimulants do not cause histamine release and are therefore seldom associated with pruritus and excoriations and also because cutaneous complications are frequently caused by the adulterants injected along with the opiates, rather than the drugs themselves. Fresh puncture sites, tattoos used to cover needle tracks, keloid formation, track marks from chronic inflammation, burns, ulcerated areas and skin popping resulting in atrophic scars, necrotizing fasciitis, acute generalized exanthematous pustulosis, fungal infections, hyperpigmentation at sites of healed abscess, puffy hands (lymphoedema with obliteration of anatomic landmarks and pitting edema absent), and histamine-related urticaria (opiates act on mast cells resulting in histamine release) may be seen.

Reducing Health Risks

Information and advice should be given to the detainee by the HCP on reducing the harm from continued drug misuse. Advice can be provided on a range of issues [33]:

- encouraging the detainee to see their general practitioner and/or attend hospital clinics to receive the appropriate care for long-term conditions.
- referral to an on-site arrest referral/drug worker (if available see below)
- information being provided about local agencies involved in counselling and treatment of substance-related problems, such as community drug and alcohol teams, treatment centres and needle exchange schemes
- advice regarding testing for blood-borne virus infections, hepatitis C and HIV, with referral for treatment if required
- information and advice about, and immunisation against, hepatitis B (and possibly hepatitis A) (see Chap. 10)
- tetanus immunisation status should be checked in people who inject drugs
- education on the hazards of injecting drugs, particularly with regard to shared injecting equipment
- education on the risks of overdose, of multiple use of substances, including alcohol, and of the variable purity of illicit drugs
- advice regarding the loss of tolerance and risk of fatality following reduction in regular use or a period of abstinence such as may occur following time in prison or residential rehabilitation
- contraception advice, reminders regarding cervical cancer screening, and safer sex advice and, where required, referral to sexual health service
- referral to dentists with oral health problems—dental caries, tooth erosion, periodontal disease.

Substance misusers who inject may have experienced a broken needle at some time in their injecting career [44]. Central embolization may occur within a few hours up to several days and this can lead to potentially fatal consequences including pericarditis, endocarditis, and pulmonary abscesses. Needle fragments need to be removed as soon as possible to avoid future complications. This may be done by the users themselves or necessitate attendance at the emergency department.

Brief interventions, whereby it is possible to provide advice about the risks inherent in a range of patterns of substance use and to advise reducing or stopping use as part of screening and assessment [45], should be used opportunistically in the criminal justice system. A person's motivation to change is important in determining the likelihood of success of any intervention [46], and such motivation may alter depending on a variety of factors. For example, negative life events such as being arrested for an acquisitive crime motivated by a need to finance a drug habit can introduce conflict in the detainee's mind about substance misuse and may increase the likelihood of successful intervention.

There is no longer a national Drug Intervention Programme (DIP) [47] in England and Wales which had the aim of identifying Class A drug (heroin and cocaine) users by testing them on charge, and directing them into drug treatment in an attempt to reduce offending behavior. Individual police forces have the discretion to opt in or out of legacy DIP powers including testing on arrest, required assessments, and restrictions on bail. Consequently, the implementation of these provisions varies from area to area. HCPs should be aware of whether there is access to

Criminal Justice Integrated Team (CJIT) workers (or equivalent) who are members of a multi-disciplinary team providing support, advice, brief and structured interventions to individuals, with substance use disorders within the criminal justice system.

Older People with Multiple Co-morbidity

There is an increasing older population with substance use disorders in the community [38, 48, 49]. HCPs may see older detainees on opiate substitution treatment (OST), as well as other medications, with complex and multiple health problems. There are a group of early onset substance users with a long history, usually of poly-substance use (heroin, crack/cocaine, tobacco and alcohol) persisting into later life. There are also late onset users of substances who may have begun using substances regularly later in life, often following stressful life events or lifestyle changes.

Prescribing

Although prompt treatment to limit or prevent the withdrawal syndrome is desirable, no central nervous system (CNS) depressant medication should be given if there is evidence of intoxication with other drugs, for example, alcohol, as many substances have an additive effect, or even, synergistic effect. Consideration of whether the detainee is fit for detention is the priority. Most individuals are not detained in police custody for very long, and therefore medical treatment may not be required. This is particularly so if there is any question that the detainee may have recently ingested substances the full effects of which may not as yet be obvious. Reassessment after a specific period should be recommended depending on the history given by the detainee and the objective examination findings.

Details of medication should be verified whenever possible. It is good practice for all new substitute opiate prescriptions to be taken initially under daily supervision [39]. In the custodial situation if the detainee is on a supervised program of therapy, one can be reasonably sure the detainee is dependent on that dose; the detainee may of course be using other illicit substances as well. Recent urine test results may be checked with the clinic to see whether methadone or other drugs are detected on screening.

With OST in particular, in the absence of withdrawal signs, confirmation of such treatment should be sought before authorizing continuation. The prescribed dose of OST may not necessarily indicate accurately the actual amount taken each day if not supervised, as part or all of the dose may be given to other individuals. If there is doubt about the daily dose, then the dose can be divided and given every 12 h. It should be remembered that giving even a small amount of opiates to a nondependent individual may be fatal. Cocaine abuse appears to accelerate the elimination of methadone; therefore, higher doses of methadone need to be prescribed to individuals on maintenance regimes who continue to abuse cocaine [50]. Any decision to

WIT.0043.0086.0431

prescribe should be made on the assessment of objective signs as opposed to subjective symptoms, and a detailed record of the history and examination should be made contemporaneously. If there is any doubt as to the interpretation of the given history, findings on physical examination, and need for prescribing then it is essential to seek advice from a senior colleague.

Good practice dictates that where treatment can be verified it should be continued as long as it is clinically safe to do so. Evidence from the National Treatment Outcome Research Study (NTORS), a prospective study of treatment outcome among substance misusers in the UK, has shown substantial reduction across a range of problem behaviors 4–5 years after patients were admitted to national treatment programs and it is important not to disrupt such programs [51]. Individuals referred from the criminal justice system have been found to have more complex offending patterns and chaotic problems, although a significant majority 73% have been in treatment before [52]. So it is important to facilitate reinitiating treatment for this "difficult group."

Specific Drugs

Pharmacodynamics refers to the effect of substances on the body, and the acute and chronic effects of substances take place at receptors (see Table 12.3). There are now seven main criteria for substance dependence (see Table 12.4). The detailed guidance on the clinical management of acute and chronic harms of the specific drugs outlined below, including the novel psychoactive substances (NPS), can be found in a variety of texts [33, 39, 53, 54]. A brief summary will be given in relation to management in police custody.

Opiate Intoxication and Withdrawal

The characteristics of the medical syndromes in opiate intoxication, overdose, and withdrawal are given in Table 12.5. Opiates such as heroin may be taken orally, more usually injected, or smoked. The start of withdrawal will vary in time with the different opioid drugs, and it should be remembered that the severity of withdrawal symptoms is influenced greatly by psychological factors [55]; the environment of a police cell is likely to exacerbate these symptoms.

Chronic administration of opiate drugs results in tolerance (Table 12.4) to effects such as euphoria mediated by the opiate receptors and to the effects on the autonomic nervous system mediated by the noradrenergic pathways. Tolerance to heroin can develop within 2 weeks of commencing daily heroin use, occurs more slowly with methadone, and may go as quickly as it develops. With abrupt withdrawal of opiates, there is a "noradrenergic storm," which is responsible for many of the opiate withdrawal symptoms (Table 12.5). Many opiate users are also dependent on benzodiazepines and concurrent benzodiazepine withdrawal may increase the severity of opiate withdrawal [57].

WIT.0043.0086.0432

Table 12.3 Primary target and main effects of addictive substances in the brain

Drug	Primary target	Main effects	Other actions
Opiates	Stimulate mOR receptor	?	Stimulate delta and kappa opioid receptors
Heroin			
Morphine/ methadone			
Buprenorphine	Less stimulation of mOR		
Stimulants			
Amphetamines	Promote dopamine release	Increase dopamine	Increase norepinephrine, serotonin, and endorphins
Cocaine	Blocks DAT	Increases dopamine	Inhibits norepinephrine reuptake
Nicotine	Stimulates nicotinic receptor	Increase dopamine	
Sedatives			
Alcohol	Simulate $GABA_A$ receptor	Increases GABA	Increases dopamine
		Reduces glutamate	
Benzodiazepines	Stimulate $GABA_A$ receptor	Increases GABA	?
Gamma Hydroxybutyrate	Stimulate GAB_A and GHB receptors	Increases GABA	Increase dopamine
Cannabinoids	Stimulate CB1 receptor	Increases dopamine	Reduces GABA and norepinephrine release
Hallucinogens			
LSD	Stimulate serotonin $5\text{-}HT_2$ receptor	Mimics serotonin	Increases dopamine
MDMA	Promotes serotonin release	Increases serotonin	Increase dopamine
		Increases norepinephrine and serotonin?	

mOR muopioid receptor, *DAT* dopamine transporter, *GABA* gamma aminobutyric acid

Treatment of Opiate Withdrawal

A careful history and thorough physical examination should be carried out to establish the nature and severity of the withdrawal syndrome prior to treatment; use of a clinical opiate withdrawal scale (COWS) may assist in the assessment [58, 59]. Symptomatic treatment of the opiate withdrawal syndrome can often be achieved using a combination of drugs such as loperamide for diarrhea; metoclopramide or buccal prochlorperazine for vomiting; mebeverine hydrochloride or hyoscine

WIT.0043.0086.0433

Table 12.4 Diagnostic criteria for substance dependence

1.	Tolerance, as defined by either of the following: (a) A need for markedly increased amounts of the substance to achieve intoxication or desired effect (b) Markedly diminished effect with continued use of the same amount of the substance
2.	Withdrawal, as manifested by either of the following: (a) The characteristic withdrawal syndrome for the substance (refer to criteria A or B of the criteria sets for withdrawal from specific substances). (b) The same (or a closely related) substance is taken to relieve or avoid withdrawal symptoms.
3.	The substance is often taken in larger amounts or over a longer period than was intended.
4.	There is a persistent desire to use the substance or unsuccessful attempts to cut down or control substance.
5.	A great deal of time is spent in activities necessary to obtain the substance, use the substance, or recover from its effects.
6.	Important social, occupational, or recreational activities are given up or reduced because of substance use. (c) The substance use is continued despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by the substance.

From: Diagnostic and Statistical Manual of Mental Disorders (DSM-5), 2013 American Psychiatric association

Table 12.5 Medical syndromes in heroin users

Syndrome (onset and duration)	Characteristics
Opiate intoxication	Conscious, sedated "nodding"; mood normal to euphoric; pin-point pupils
Acute overdose	Unconscious; pin-point pupils; slow shallow respirations
Opiate withdrawal	
Anticipatory 3–4 h after the last fix (as acute effects of heroin subside)	Fear of withdrawal, anxiety, drug-craving, drug-seeking behavior
Early 8–10 h after last fix	Anxiety, restlessness, yawning, nausea, sweating, nasal stuffiness, rhinorrhea, lacrimation, dilated pupils, stomach cramps, increased bowel sounds, drug-seeking behavior
Fully developed 1–3 days after last fix	Severe anxiety, tremor, restlessness, piloerection (cold-turkey), vomiting, diarrhea, muscle spasms (kicking the habit), muscle pain, increased blood pressure, tachycardia, fever, chills, impulse-driven drug-seeking behavior
Protracted abstinence	Hypotension, bradycardia, insomnia, loss of energy and appetite, stimulus-driven opiate cravings

From: Ling and Wesson [56]

butylbromide for abdominal cramps and paracetamol or nonsteroidal anti-inflammatories for generalized aches. However overall there is low efficacy of non-opioid drugs in treating opioid withdrawal with only benzodiazepines having a moderate positive effect [60]. Benzodiazepines are not recommended in the routine treatment of opiate withdrawal in this setting as such drugs may affect cognition and therefore fitness to be interviewed.

WIT.0043.0086.0434

Substitution treatment may be required in more severe cases of opiate dependence using a choice of methadone, buprenorphine, or dihydrocodeine [61]. As street heroin varies in purity, the starting dose cannot be accurately estimated on the basis of the amount of street drug used. Therefore, substitution therapy should be titrated against the symptoms and signs of withdrawal. For example, dihydrocodeine may be commenced in a dose of 90–120 mg three times a day, with the dose being increased if the patient has demonstrable clinical signs of opiate withdrawal [62].

Methadone

Methadone is a synthetic opioid drug, used widely in the treatment of opioid dependence with a long duration of action so it can be given once a day. There are a number of formulations including liquid, tablet and injectable. Liquid methadone for the treatment of opioid dependence is available in a number of strengths: the usual form is methadone oral solution 1 mg/mL, which is typically green, although there is a color-free mixture; methadone oral concentrate, not commonly used, is available in two strengths: 10 mg/mL (blue) and 20 mg/mL (brown).

It is important to remember that the effect of a particular dose of methadone will depend on the individual's tolerance to opioids. Tolerance can develop within 2 weeks of commencing daily use but also disappears as quickly as it develops so that a previously safe dose may prove fatal. Peak concentration is achieved 4 h after consumption and the drug has a half-life of 10–25 h after a single dose and 13–55 h after repeated doses. It is highly lipid soluble and it takes several repeated doses before tissue reservoirs are full. As long as it is clinically safe to do so, prescribed methadone, from a community drug/primary care center should be continued while in custody, as long as it is clinically safe to do so.

Buprenorphine

Buprenorphine is an opioid with mixed agonist-antagonist properties, less of a risk in overdose when taken alone. It is taken sublingually, and self-administration of the drug in the custodial environment must be personally supervised by a suitably qualified HCP who should observe the patient for 5 min to ensure that the drug has fully dissolved [63]. This is essential to prevent hoarding and further misuse [64], for example, by snorting in prison. The tablets are available in a variety of strengths and also in combination with naloxone. Different formulations of buprenorphine including e.g. freeze-dried wafer formulations; and depot preparations are now available. Peak concentration is 90–150 min, with peak effects 1–4 h post dose. The duration of action is related to dose—with a low dose of 2–4 mg effects last for up to 12 h, whereas with a higher dose of 16–32 mg effects may last for up to 48–72 h. Buprenorphine is usually administered once a day because of its long duration of action. It is essential that prescribed buprenorphine from a community drug/primary care center, should be continued in custody, as long as it is clinically safe to do so. Precipitation of opioid withdrawal can occur in someone commencing

WIT.0043.0086.0435

buprenorphine who is dependent on large doses of opioids or other opioid analgesics if this is started when the person is not in withdrawal.

Naloxone

Naloxone is an opioid antagonist that reverses the effects of severe intoxication (Table 12.5). The use of naloxone may precipitate withdrawal in addicted patients, but in initial doses of 0.4–0.8 mg it is relatively safe, with little risk of vomiting, seizures, hypotension, hypertension, or cardiac arrest [65]. The half-life of naloxone is shorter than that of most opiates, and therefore a period of observation in the hospital is required after administration. It is recommended to give half the dose intravenously and half intramuscularly (absorption is slower and the antidotal activity prolonged); this is useful, as often individuals discharge themselves once awakened. It is recommended to give oxygen or bag-valve-mask ventilation where RR < 10/min or SpO_2 < 92% (on air) [66]. Where severe opioid intoxication is suspected, an emergency ambulance must be called immediately and naloxone given.

Intranasal naloxone has been used in the prehospital care environment and found to be a safe and effective first line prehospital intervention in reversing the effects of an opioid overdose, avoiding fatalities, and helping to reduce the risk of needle stick injury [67, 68]. Nasal naloxone is now available in the UK as Nyxoid® a single-dose nasal spray containing 1.8 mg of naloxone (as hydrochloride) in a 0.1 mL solution (two nasal sprays are included in the carton) [69]. It is indicated for emergency administration for known or suspected opioid overdose in adults and adolescents aged 14 years and over and there should be a response within 2–3 min of administration. Heroin may be taken in combination with cocaine ("snowball"), and the use of naloxone in this situation may precipitate ventricular dysrhythmias [70, 71].

Benzodiazepines

Benzodiazepines produce physical and psychological dependence and are only recommended for limited periods (4 weeks) [72]. The drugs are commonly misused either illicitly, which usually involves high doses, or by persistent therapeutic use at a lower dose. The pharmacologic properties of the benzodiazepines are hypnotic, anxiolytic, muscle relaxant, and anticonvulsant and are produced by enhancing gamma-aminobutyric acid (GABA) transmission. There are increasing reports of the use of illicitly manufactured alprazolam, etizolam and diclazepam, often used by young people with alcohol, the concentration of drug in the pills varying widely [73].

Manifestations of intoxication and withdrawal are given in Table 12.6. Tolerance usually develops after continuous use, slowly for those drugs that have a long half-life but more quickly for the short-acting drugs. Benzodiazepines are well absorbed from the gastrointestinal tract after oral administration; food can delay the rate but not the extent of absorption.

WIT.0043.0086.0436

Table 12.6 Manifestations of sedative-hypnotic drug intoxication and withdrawal

Mild	Sedation, disorientation, slurred speech, ataxia, nystagmus, amnesia
Severe	Coma, hypoventilation, hypotension, hypothermia, depressed or absent corneal, gag, and deep tendon reflexes
Withdrawal	Anxiety, insomnia, irritability, agitation, anorexia, tremor, disordered perceptions, seizures

Side effects of use include drowsiness, memory impairment especially anterograde amnesia at therapeutic doses, the risk increasing at high dosages. There is controversy about whether benzodiazepine use alone can result in disinhibited or impulsive behaviour [72]. Anxiolytics lower tolerance to alcohol and in high doses produce mental confusion similar to alcohol intoxication. The interaction between alcohol and benzodiazepines results in a potentiation of the CNS effects. In general, however, they have a very high toxic-therapeutic ratio and doses 15–20 times therapeutic dose may not cause serious side effects [74].

Sudden cessation of benzodiazepines can lead to a recognized withdrawal syndrome with anxiety symptoms, disordered perceptions, and major complications such as seizures and psychosis. A long-acting benzodiazepine such as diazepam or chlordiazepoxide is preferable in treating symptoms of withdrawal and preventing the major complications.

Flumazenil is a specific benzodiazepine antagonist used for the reversal of benzodiazepine-induced sedation and coma. When overdosage is suspected, it can be used in patients who would otherwise need intubation and ventilation [75] but care should be taken when mixed overdoses are suspected [76]. Complications such as convulsions, dysrhythmias, heart block, and cardiac arrest suggest that its use in the prehospital environment should not be encouraged [77].

Z-drugs

Z-drugs (zaleplon, zolpidem and zopiclone) non-benzodiazepine hypnotic drugs have similar effects to benzodiazepines and are relatively safe unless mixed with other central nervous depressants. Physical and psychological dependence occurs and there may be impairment of memory and cognition.

Pregabalin and Gabapentin

Pregabalin and gabapentin have been increasingly misused in recent years [78]. These drugs are used in the treatment of epilepsy, generalized anxiety disorder, for the relief of neuropathic pain, postherpetic neuralgia, diabetic peripheral neuropathy, fibromyalgia, and as an adjunct therapy for partial seizures. Clinical effects include euphoria, improved sociability, and relaxation. Adverse effects include significant CNS depression resulting in drowsiness, sedation, respiratory depression, and at the extreme, death. The majority of related deaths are in those who are also

WIT.0043.0086.0437

taking opioids. Withdrawal effects have been described including headache, nausea, anxiety, diarrhoea, flu-like illness, convulsions, nervousness, depression, pain, hyperhidrosis and dizziness suggestive of physical dependence. Detainees receiving prescribed pregabalin or gabapentin should have their treatment continued whilst in police custody as long as it is clinically safe to do so. Detainees misusing these drugs should be treated symptomatically.

Barbiturates

Barbiturates are used in the treatment of epilepsy and for the induction of anesthesia. They became less commonly misused following the introduction of benzodiazepine drugs but may be used by polydrug users. Mild intoxication may result in slurred speech, over sedation, ataxia, and nystagmus, while severe intoxication may present with coma, absent reflexes, hypothermia, hypotension, and respiratory depression. There is a narrow margin between therapeutic dose and serious toxicity. Physical and psychological dependence occurs, and the withdrawal syndrome is similar to that of benzodiazepine withdrawal, with a greater risk of seizures. Benzodiazepines may be used to prevent the withdrawal syndrome associated with barbiturates.

Illustrative Case *An elderly male was found collapsed in the street with a suspected opiate overdose and was taken to hospital by police. He was wanted on a warrant so after assessment at the hospital he returned to custody. The HCP was called to assess whether he was fit to be detained. The male gave a history of epilepsy currently well controlled on phenobarbitone. He also said that he was dependent on heroin. On examination he was found to be drowsy with impaired co-ordination and an unsteady gait. Further discussion with the patient revealed that he had taken an overdose of his prescribed drug phenobarbitone as he had no access to heroin and was experiencing symptoms of opiate withdrawal. The HCP telephoned the local poisons centre for advice and it was recommended that he return to hospital for a further assessment/observation.*

Solvents

Volatile substance abuse (VSA) is the deliberate inhalation of fumes given off by volatile substances (solvents) to achieve intoxication and can occur at any age but is a particular problem among adolescents. Adhesives, aerosols, anesthetics, dry cleaning agents, fuel gases, nail varnish, and paint stripper are among the substances inhaled, either directly from their containers, from a plastic bag placed over the nose and mouth, from impregnated rags, or sprayed directly into the mouth.

Regular users may have nasal sores, “glue-sniffer’s rash” (perioral dermatitis), and have the odor of solvents on their breath. Acute effects begin within minutes [79] and may last 15–45 min; persistent abnormalities may occur in severe chronic abusers (Table 12.7) [80].

WIT.0043.0086.0438

Table 12.7 Manifestations of solvent intoxication and abuse [206]

Mild	Euphoria
	Disinhibition
	Dizziness
	Slurred speech
	Lack of coordination
	Sneezing and coughing
Moderate	Lethargy, stupor
	Hallucinations
	Nausea, vomiting
	Diarrhea
	Nystagmus
	Ataxia
	Tremors
	Myalgias
	Paresthesia
Severe	Coma
	Seizures
Chronic	Cerebellar syndrome: ataxia, nystagmus, tremor (toluene)
	Fatigue, difficulty in concentrating
	Parkinsonism (toluene)
	Peripheral neuropathy: symmetrical, motor, mainly involving hands and feet (*n*-hexane and naphtha)

Table 12.8 Deaths from volatile substance misuse

Acute	Direct	Immediate
		Postponed
	Indirect	Trauma
		Aspiration
		Asphyxia
		Drowning
Delayed	Direct	Liver failure
		Renal failure
		Liver tumors
		Bone marrow depression
		CNS involvement

From Shepherd [78]

Most acute direct VSA-related deaths result from cardiac dysrhythmias due to "sensitization" of the myocardium to adrenaline; deaths may also occur from indirect effects or may be delayed (Table 12.8) [81]. Animal experiments confirm that myocardial sensitivity may continue for hours after the initial inhalant exposure [82]. Tolerance may develop, and psychological dependence after long-term use and a withdrawal syndrome similar to delirium tremens has been described [83].

WIT.0043.0086.0439

Lysergamides, Tryptamines, and Phenethylamines

Hallucinogenic (psychedelic) drugs include lysergamides (LSD), tryptamines (mushrooms), and phenethylamines (mescaline, 2CB, 25B-NBOMe) [53].

Lysergic acid diethylamide (LSD) is usually taken orally in a dose of 75–100 μg with effects occurring within 60 min. There is a recovery period of 10–12 h where there may be periods of normal perception and cognition alternating with degrees of intoxication, which may affect fitness for interview.

Acute effects include tachycardia, hypertension, pyrexia, dilated pupils, sweating, flushing. Emotional lability, euphoria and anxiety, distortion of time, visual and auditory illusions (although true hallucinations can occur), and synesthesia, with a mixing of the sensory input—"seeing" sounds or "hearing" smells—may all occur [84].

Both enjoyable and unpleasant effects, a "bad trip," may occur in a first-time user or with repeated use. Psychiatric adverse effects have been described, which include anxiety and panic attacks, self-destructive behavior, hallucinations, acute psychosis, and major depressive reactions. Polydrug users may use benzodiazepines to alleviate anxiety and panic attacks. Hallucinogen persisting perceptual disorder (HPPD) and flashbacks may occur. Dependence does not occur and there is no recognized withdrawal syndrome. Sensitivity to the effects drug may be reduced (tachyphylaxis).

The use of hallucinogenic mushrooms, which grow wild in many areas of Europe [85] and in the United States, though more commonly are cultivated, has been increasing. Mushrooms are usually eaten or made into tea. The effects due to tryptamines, psilocybin and psilocin, are dependent on dose and the individual reaction and sensitivity to psilocybin, previous experiences and the setting. The effects [86] range from mild feelings of relaxation, giddiness, euphoria, visual enhancement (seeing colours brighter), visual disturbances (moving surfaces, waves), to delusions, altered perception of real events, images and faces, or real hallucinations. The sensory distortions may be coupled with restlessness, incoordination, feelings of anxiety, impaired judgement of time or distance, sense of unreality or even depersonalisation. These effects may be termed 'bad trips' by users and can also involve panic reactions and psychosis-like states. Physiological effects may include dizziness, nausea, weakness, muscle aching, shivering, abdominal pain, dilation of pupils (mydriasis), mild-to-moderate tachycardia, tachypnoea, hypertension, but the body temperature remains normal.

Ecstasy (MDMA) [51]

3,4-Methylenedioxymethamphetamine, or "ecstasy," is commonly taken in an oral dose of 75–120 mg as a recreational drug within the dance culture or "rave" scene for its central stimulant and psychedelic effects (Table 12.9). The effects last for 4–6 h with tolerance developing to the acute effects. Problems occur because of its use with other drugs for example alcohol, cocaine, and ketamine. There is little evidence for

WIT.0043.0086.0440

Table 12.9 Effects of MDMA (ecstasy)

Psychological	Euphoria, heightened awareness, improved sense of communication
Neuropsychiatric	Anxiety, insomnia, depression, paranoia, confusion, panic attacks, psychosis
Chronic	Depression, drowsiness, anxiety, panic disorder, aggressive outbursts, psychosis, memory disturbance
Medical	Tachycardia, hypertension, dry throat, bruxism, trismus, sweating, pyrexia, nausea, vomiting, anorexia, loss of coordination with ataxia, dilated pupils, nystagmus, hot and cold flushes, hyperreflexia

Table 12.10 Summary of the severe acute harms following the use of ecstasy

Hyperthermia/hyperpyrexia
Serotonin syndrome
Dilutional hyponatremia and hyponatremic encephalopathy
Acute psychiatric presentations: anxiety, panic, psychosis
Other isolated physiological syndromes: cardiac events, liver failure, pneumomediastinum

long-term physical dependence on MDMA, because of the different pharmacological action of MDMA having more effect on brain serotonin and less on brain dopamine function, but some withdrawal effects such as low mood are frequent.

Adverse effects (Table 12.10) such as a polydipsia, hyponatremia, and catatonic stupor have been reported [87, 88]. An acute rise in antidiuretic hormone (arginine vasopressin [AVP]) accompanied by a small fall in plasma sodium has been shown following the ingestion of MDMA. Therefore, in view of the risk of hyponatremia, individuals who take such drugs should avoid drinking fluid in excess of the body's requirement. This may be difficult because MDMA reduces the perception of thirst and impairs judgment [89], and people tend to overcompensate and consciously overdrink.

Regular users may habitually use chewing gum to overcome the effects on the jaw muscles. The clenching of teeth in the acidic environment caused by carbonated (fizzy) drinks will result in an increased likelihood of tooth wear on the back teeth [90]. Other adverse effects have been described including jaundice and hepatotoxicity [91]; flashbacks and psychosis [92]; pneumomediastinum [93]; urinary retention [94]; hyperthermia; coagulopathy [95]; rhabdomyolysis; and cardiovascular complications resulting in death [96–98]. MDMA differs from other stimulants, such as cocaine and amphetamines, in that it rarely causes paranoid feelings or aggression although the development of chronic paranoid psychosis has been described after heavy misuse of the drug [99] and the serotonin syndrome [100, 101] (altered mental state, hyperthermia, and autonomic dysfunction) has also been reported following MDMA ingestion. With regard to chronic psychological effects, there may be cognitive deficits affecting memory and recall from serotonergic neurotoxicity. 3,4-Methylenedioxymethamphetamine (MDEA) is an analog of MDMA with similar effects. 3,4-Methylenedioxyamphetamine (MDA) and *para*-methoxyamphetamine (PMA) may also be used as recreational drugs.

WIT.0043.0086.0441

Cocaine and Crack

Cocaine occurs naturally in the leaves of the coca plant Erythroxylum coca, which grows predominantly in South America. Cocaine hydrochloride is a white powder that is usually snorted but can be taken orally. Crack is prepared by mixing cocaine hydrochloride with sodium bicarbonate and water and heating it. The cocaine base precipitates out and forms small "rocks" as it cools. Crack may be smoked in a pipe or heated on foil with the vapor inhaled. Both crack and cocaine may be injected.

The onset of action and plasma half-life varies depending on the route of use, very rapidly if taken intravenously or smoked compared with when snorted. The duration of effects will also vary with route of administration. Ingestion of stimulant drugs such as cocaine or amphetamine results in activation of the sympathetic nervous system with resulting euphoria followed by irritability, depression, insomnia, and paranoia (Table 12.11).

Tolerance occurs to the psychological effects of cocaine. Deaths may occur, most commonly from cardiac dysrhythmias, acute coronary syndrome, excited delirium, and stroke. Cocaine is atherogenic and induces coronary artery constriction [102]. Chronic effects include perforation of the nasal septum and rhinorrhea, and long-term use may result in a range of psychiatric problems and vascular diseases.

Cocaine produces a physical and psychological dependence, the severity of which will vary depending on the method of administration, being more severe if the drug is smoked or injected than if snorted. Dependence may result in a particular strong craving for the drug, followed by a withdrawal syndrome or "crash" with irritability, insomnia, depression, and anxiety on cessation. In conditions of police custody, the depression and inability to sleep may lead to acts of self-harm and suicide, and close supervision may be required, with consideration given to prescribing hypnotics and antidepressants.

Amphetamine-Type Stimulants (ATS)

ATS such as amphetamine and methamphetamine are usually found as white powders taken nasally, orally, intravenously, or with methamphetamine smoked. Clinical effects are similar to those of cocaine (Table 12.11), although amphetamine has a longer half-life of 6–12 h, so the duration of euphoria is longer. "Ice" is a very pure form of methamphetamine hydrochloride (98–100% pure), which is usually smoked like crack cocaine.

Table 12.11 Effects of cocaine and amphetamine intoxication

Initial low dose	Euphoria, insomnia, dry mouth, hyperthermia, tachycardia, hypertension, increased respiration, sweating, dilated pupils
With increasing dose	Irritability, impulsivity, aggressiveness, agitated delirium, paranoia, delusions, seizures

Tolerance occurs with long-term use and psychological dependence with a withdrawal syndrome of depression, anxiety, and sleep disturbance. "Speed runs" describe repeated use over a period of days with several grams of amphetamine used daily. At the end of the "run," the user may sleep for several days. Alcohol, sedative-hypnotic drugs, and heroin may be used to reduce the anxiety caused by amphetamine or, alternatively, amphetamine may be used to reduce the sedative effects of such drugs.

The diversion and abuse of methylphenidate, used in the treatment of attention deficit hyperactivity disorder (ADHD), has also been reported [103].

Serotonin syndrome may occur with the use of ATS and this is a potentially life-threatening reaction. Therapeutic drugs, for example, antidepressants such as selective serotonin reuptake inhibitors (SSRIs), monoamine oxidase inhibitors (MAOIs), tricyclic antidepressants, opiate analgesics including tramadol, are associated with the serotonin syndrome.

Illustrative Case *A female who had a history of depression and drug use with previous admissions to psychiatric hospitals, was found by police in an agitated state. The police used their powers under section 136 of the Mental Health Act 1983 to remove her to a place of safety, in this case a police station. She was agitated and violent, and was put in a cell in a 'safety suit'. A doctor observed her through the wicket but did not enter the cell and said he would call the community mental health team. She was seen to be perspiring and had removed some of her clothes. An hour later she was slumped in a corner of the cell and was found to be unresponsive. Attempts at resuscitation in the police station were unsuccessful and she was pronounced dead. The cause of death was given as serotonin syndrome.*

Chemsex is a term used mostly in relation to men who have sex with men (MSM) to describe the use of drugs during sexual activity, which is increasingly associated with unsafe sexual practices, and sexually transmitted infections [104]. Three drugs are associated with this behaviour—methamphetamine, mephedrone and gamma hydroxybutyrate. These drugs cause sexual disinhibition and high-risk sexual practices.

Khat

Khat consists of the young leaves of the Catha edulis plant and is usually chewed for its stimulant effect when fresh but may be drunk as an infusion of leaves. In the UK khat is consumed almost exclusively within communities from East Africa and the southern Arabian Peninsula [105]. The main components are cathinone and cathine, with effects similar to those of amphetamine, resulting in euphoria, increased alertness, anorexia; anxiety and insomnia may occur.

The Advisory Council on the Misuse of Drugs (ACMD) noted that khat use has the potential to develop into dependency but this is much less likely than dependency on stimulants like amphetamine, and more like the type of dependency seen with caffeine [106]. Withdrawal symptoms are reported, but do not necessarily imply a withdrawal syndrome and are more comparable to a 'morning after' experience.

WIT.0043.0086.0443

Marijuana

Marijuana is the most commonly used illicit drug in the UK and the United States. It is obtained from the Cannabis sativa plant, and the principal active ingredient, accounting for the majority of effects, is delta-9-tetrahydrocannabinol (THC). There are a number of forms, including hashish (a resin), herbal cannabis (a green-colored preparation made from the leaves of the plant), and "skunk" or sinsemilla a potent form of the cannabis plant with high levels of THC on average 14.2% (as opposed to 6.3% in resin) [107], which is grown indoors using hydroponic techniques, in nutrient-rich liquids rather than soil, under grow lights or greenhouse conditions. The onset of effects is reported as being more rapid, and the hallucinogenic properties are heightened. Cannabis resin usually contains cannabidiol (CBD) thought to be protective against some of the dangerous effects of THC; sinsemilla does not contain CBD.

Cannabis is usually smoked but can be ingested as, for example, "cannabis cookies." One "joint" typically contains 10–30 mg of THC and has an onset of action of 10–20 min with effects lasting 2–3 h. Acute effects include conjunctival injection; rise in blood pressure; an increase in heart rate; sedation and euphoria, occasionally panic attacks and paranoia in some users; altered perceptions of space and time; impaired learning and memory; difficulty problem solving; and loss of coordination.

Tolerance has been shown to develop to many effects of cannabis including the "high" with chronic use, and an abstinence syndrome has been described with disturbed sleep, decreased appetite, restlessness, irritability, and sweating. Withdrawal symptoms are usually mild and short-lived, although they may be more severe in heavy regular users and especially in those who are heavy users of tobacco.

Cannabis increases the risk of psychosis especially in frequent users and may be responsible for transient exacerbations in psychotic features in those with significant mental illness. Psychotic episodes may be precipitated by relatively small quantities of high potency cannabis.

Synthetic cannabinoid receptor agonists [108] may present as vape fluids, impregnated on paper, or sprayed on flammable plant material sold as herbal tea or incense. The desired effects which occur within minutes of smoking, include relaxation, euphoria, disinhibition, but these may be followed by adverse effects such as convulsions, anxiety, bizarre behavior, amnesia, confusion, panic attacks, hallucinations, paranoia delusions, and psychosis. Duration of action is variable between 1 and 8 h. There is evidence that chronic use may be associated with tolerance which develops more quickly than for other forms of cannabis. Symptoms of intoxication are usually self-limiting and resolve spontaneously. Management of toxicity is symptomatic and supportive.

Image and Performance Enhancing Drugs (IPEDs)

IPEDs are substances used with the intention of altering or improving a person's appearance or abilities [109]. There are a range of drugs that may be used:

WIT.0043.0086.0444

- Anabolic steroids and gym drugs
- Nootropics—modafinil, methylphenidate, amphetamine (used to increase cognitive functioning by students)
- Botox, dermal fillers and tanning drugs (melantan)

Any of these drugs given by injection may lead to potential health risks from direct damage from injection, blood-borne viruses, and infections or inflammation at injecting sites, especially with counterfeit substances.

Anabolic (anabolic androgenic) steroids may be taken orally or intramuscularly by body builders or other individuals who want to enhance their physical appearance. Research has shown that injections of testosterone enanthate increase muscle size and strength, especially when combined with exercise [110]. To achieve the desired effect, different steroids are taken in cycles, with rest periods in between, a regime known as "stacking," or, alternatively, increasing doses of the same steroid are taken, a so-called drug pyramid [111]. Most of the steroids sold in the UK are counterfeit rather than produced by legitimate pharmaceutical companies. Consequently, they may contain a different steroid from the one indicated on the bottle, and scant reliance can be placed on the reported dose as they may have little or no steroid in them at all [112].

General effects of anabolic steroids [109, 112] include baldness, acne, raised blood pressure, fluid retention, and a reduction in high-density lipoprotein cholesterol. Long-term effects include liver and kidney damage. Gynecomastia may occur, and the prostate gland may swell, resulting in impaired micturition. Most of these effects are dose-dependent and more likely with prolonged administration.

While the drug is being taken, there is a significant reduction in testosterone production by the testes so that sperm output and quality are decreased, and a return to normal can take many months after drug use is stopped. The effect on sex drive is variable, but overall it seems that the sex drive increases at the beginning of a steroid-using cycle, and then decreases to below normal after several weeks of use. Drive may remain below normal levels even after the drug is stopped until such time as the testes start producing testosterone again. There may also be a reduction in size of the testicles [113].

In women menstrual irregularities are reported, with permanent enlargement of the clitoris. There may also be growth of facial and body hair, male pattern baldness, and decreased breast size. Abuse of sex steroids by recreational body builders may be an unrecognized cause of subfertility [114].

Liver function tests may show abnormalities that usually return to normal once the drug is stopped. Drug-induced jaundice can be caused by temporarily impaired excretory function, and peliosis hepatitis, in which the liver tissue is replaced by blood-filled cysts, may occur, as can liver tumors [115].

Initial use may result in stimulatory effects such as increased confidence, decreased fatigue, heightened motivation, agitation, irritability, and insomnia, which may progress to argumentative and aggressive behavior and major mood disturbances including depression, mania, and hypomania [116, 117]. "Roid rage," which may be associated with violent crimes [118], seems to require a high dose of steroids over several weeks, as may occur when "stacking."

WIT.0043.0086.0445

Other Body Building Drugs

Polypharmacy is common among anabolic steroid users [119]. Other drugs may be used by body builders, including tamoxifen to reduce or prevent gynecomastia; diuretics to counteract the fluid retention caused by anabolic steroids; thyroxine to increase the rate of metabolism, which might theoretically increase the ability of anabolic steroids to boost physical strength [120]; and beta human chorionic gonadotropin to alleviate testicular atrophy [121]. Nalbuphine (Nubain) is an opioid agonist/antagonist analgesic used for the treatment of moderate to severe pain, and dependence has been reported associated with anabolic steroid use [122].

Furthermore, there has been a case report of a 21-year-old body builder who was admitted after taking excessive amounts of insulin intravenously; apparently insulin is advertised in body building magazines as having anabolic properties [123]. The recreational use of caffeine to toxic levels has been reported in a body builder who presented with a grand mal seizure [124]. Clenbuterol, which is a sympathomimetic agonist (used as an oral bronchodilator in some European countries but not licensed for human use in the UK or the United States), is said to have an "anabolic-like" effect but at high dose may cause cardiac dysrhythmias, tremor, and serious hypokalemia [125].

Gamma-Hydroxybutyrate and Gamma-Butyrolactone

Gamma-hydroxybutyrate (GHB) is a naturally occurring substance in the human brain structurally related to GABA [126]. Gamma-butyrolactone (GBL) is converted to GHB in vivo post ingestion. GHB has been used as an anesthetic (although it has little analgesic effect), to alleviate narcolepsy, and to treat alcohol and opiate dependence [127]. It is available as a colorless, odorless liquid, powder, or capsule taken orally, rarely injected. GHB is rapidly absorbed, with peak plasma concentrations occurring after 30–60 min following oral administration. It has a half-life of 20–30 min [128], and effects can last from 45 min to 8 h [129].

Initial effects include euphoria followed by profound sedation, confusion, agitation, and amnesia; nausea, vomiting, and diarrhea; ataxia, seizures, hypotonia, and tremor; vertigo and dizziness; bradycardia, hypotension, and hypothermia; coma; and respiratory collapse.

There is a narrow margin between intoxication and coma [130], and the clinical effects are potentiated by use of other CNS depressant drugs such as alcohol, opiates, benzodiazepines, and neuroleptics [131]. Tolerance and physical dependence after high-dose use can develop with a withdrawal syndrome, which may include insomnia, muscular cramping, tremor, and anxiety [127]. Symptoms of withdrawal from GHB are broadly similar to those for alcohol, although of a more rapid onset, and can be treated symptomatically or with benzodiazepines or baclofen [53]. A rapid deterioration into delirium may occur in more frequent high-dose dependent users. Seizures have been reported, though less commonly than with alcohol withdrawal [132]. It may be difficult to manage in custody so hospital admission should be considered.

WIT.0043.0086.0446

Illustrative Case *Stephen Port was convicted in 2016 for the murder of four men after administering fatal doses of GHB* [133]. *He was aroused by the passivity of his victims (somnophilia). The bodies of three young men, in their 20s, were found in a churchyard; all had bottles of GHB in their pockets* [133]. *Somnophilia, the desire to have sex with an unconscious, sleeping or comatose person, who is unable to respond is a paraphilia, and is distinct from cases where a substance is administered to a victim in order to take advantage of them* [134].

Ketamine

Ketamine is a commercially available anesthetic for intravenous and intramuscular use. It is commonly used for recreational purposes. It is a predominately a sedative drug but has dissociative, anesthetic, psychostimulant and analgesic actions [135]. Ketamine is a member of a group of compounds known as arylcyclohexylamines, this group also includes phencyclidine and methoxetamine. These substances produce a wide range of effects but primarily they all act as non-competitive antagonists at glutamate receptors of the *N*-methyl-D-aspartate (NMDA) sub-type [135].

It is available illicitly most commonly in powder form, occasionally as a liquid, but can also be found as a tablet [53]. It usually taken intranasally ("snorted"), but also orally, smoked, and by the intravenous route. The onset of effects depends on the route of administration: intranasally within 5–30 min, intravenously within 30 s and last about 30 min. Tolerance develops after repeated use, with a decreased duration of effect [53].

Ketamine has a wide margin of safety unless taken in combination with other drugs. A dose-dependent depression of respiration may occur, and this can be a particular problem when taken with other respiratory depressant drugs such as benzodiazepines, alcohol, or opiates occasionally resulting in death [136, 137].

Physical effects may include hypertension, palpitations, nausea, and vomiting, slurred speech, nystagmus, lack of coordination, and seizures. On recovery, "emergence phenomena" may occur, with psychological dissociation or out of body (flying or floating) sensations, confusion, hallucinations, synesthesia, and depersonalization [138]. Such dissociative states may result in the individual becoming divorced from reality, and these effects, coupled with possible loss of coordination and pronounced analgesia, can result in serious accidents to users. Ketamine has been found to induce acute and severe impairment of working, episodic, and semantic memory when used frequently [139]; some of these effects have continued 3 days after drug ingestion [140]. Such cognitive impairment may impact on a detainee's fitness for interview. There is currently little evidence about physiological withdrawal but a psychological withdrawal syndrome including anxiety, drug craving, tremulousness and palpitations has been described [135].

Ketamine use is associated with damage to the urinary system—ketamine induced uropathy [141]. This may result in dysuria, painful hematuria, urge incontinence, frequency and urgent urination, nocturia, obstruction of the urinary tract.

Alkyl Nitrites

The alkyl nitrites are volatile yellowish clear liquids that have a distinctive sweet smell. All the nitrites have vasodilatory properties and are used as a euphoric relaxant within the dance culture and to relax the anal sphincter and enhance sexual performance. The effect of inhaling the vapor, usually from the bottle or poured onto a cloth, is instantaneous and very short-lived, resulting in a "rush," but adverse effects such as dizziness, flushing, tachycardia and palpitations, headache, cold sweats, and hypotension may occur [142, 143]. Swallowing of volatile nitrites as opposed to inhaling them may result in severe methemoglobinemia [144, 145].

Novel Psychoactive Substances

Novel psychoactive substances (NPS), previously known as 'legal highs' [146], are constantly being identified see Table 12.12. There have been differing legislative strategies with regard to these substances in various jurisdictions. In the UK NPS have been banned collectively under the Psychoactive Substances Act in 2016. As with all illicit substances there will be variation in the quality of content and dose received by an individual and the effects may be unpredictable depending on individual tolerance and where the drugs have been used in combination with other substances, including alcohol. HCPs should have a low threshold for early referral to an emergency department. Public Health England have a website for healthcare professionals to report cases of suspected harm with illicit substances: https://report-illicit-drug-reaction.phe.gov.uk/. Use of NPS may influence a detainee's fitness for interview and a period of rest may be required before any interview takes place.

Table 12.12 Novel Psychoactive Substances (adapted from [33])

Depressants	GHB, GBL
	Nitrous oxide
	Dissociative drugs Ketamine Methoxetamine
Stimulants	Cocaine, synthetic cocaine derivatives Piperazines Amphetamine-type substances Methamphetamine MDMA, MDA, PMA, PMMA Mephedrone Ethylphenidate Synthetic cathinones Pipradrols and derivatives
Hallucinogens	Lysergamides LSD Tryptamines Phenethylamines
Emerging drugs	New benzodiazepines
	New synthetic opioids
	Others

Alcohol

Alcohol may be involved in crime in two ways: alcohol-defined offences such as 'drunkenness' offences (drunk and disorderly/drunk and incapable), or driving with excess alcohol (Chap. 14); or offences where alcohol may have been involved, e.g. the offender was under the influence of alcohol at the time of the offence.

Crime statistics show a clear association between alcohol intake and criminal behavior, the association being most marked in relation to violent crimes. The Crime Survey England and Wales covering 2016/2017 found that in 46% of all violent incidents victims believed offenders to be under the influence of alcohol [147]. Alcohol was a particularly prevalent factor in violent incidents between strangers in figures from 2013/2014, 64% of which were perceived to be alcohol-related [148]. In Scotland the figure of alcohol-related violent crime was 42% in 2016/2017; this is almost 100,000 alcohol related violent crimes each year [149]. In Scotland in 22% of violent crime the victim had been drinking [149] and 20% of prisoners report being drunk at the time of their offence [150].

The UK Government published a Crime Prevention Strategy in 2016 recognizing that the relationship between alcohol and violence is complex and the link between alcohol and non-violent or acquisitive crime is less well developed [151].

Alcohol is important in clinical forensic medicine because of its link with criminal activity and by virtue of the significant role it plays in a large number of assessments regarding fitness for detention [35, 36, 152, 153]. In police custody in Scotland 18–34% of detainees have alcohol problems mostly at the dependency end of the spectrum [154]. Accordingly, a thorough understanding of the metabolism, effects, and problems associated with alcohol is essential for any HCP practicing in this field, not least because the detainees with alcohol problems, particularly those with gross intoxication, are an extremely vulnerable group for whom police custody may be inappropriate [155]. This is particularly important when assessing an intoxicated detainee in police custody. Indeed, the HCP's first duty in examining such individuals should be to exclude pathologic conditions that may simulate intoxication, as failure to do so may lead to deaths in police custody [156].

Alcohol use disorder (AUD) has been defined in DSM 5 (Table 12.13).

The Metabolism of Alcohol

Ethanol, hereafter referred to as alcohol, is produced by the fermentation of sugar by yeast, a process that halts at a concentration of alcohol by volume of about 15% because of the death of yeast above these levels. There is wide variation in the alcohol content of different alcoholic beverages. HCPs must bear this in mind when trying to assess intake of alcohol.

One unit in terms of an alcoholic drink in the UK is 8 g of alcohol. In the European Union there is a requirement [157] for the labelling of alcohol content of beverages of higher than 1.2% alcohol by volume (ABV). Labelling requirements are required in many jurisdictions [158].

WIT.0043.0086.0449

Table 12.13 DSM 5 Alcohol Use Disorder (AUD)

1	Alcohol is often taken in larger amounts or over a longer period than was intended.
2	There is a persistent desire or unsuccessful efforts to cut down or control alcohol use.
3	A great deal of time is spent in activities necessary to obtain alcohol, use alcohol, or recover from its effects.
4	Craving, or a strong desire or urge to use alcohol.
5	Recurrent alcohol use resulting in a failure to fulfil major role obligations at work, school, or home.
6	Continued alcohol use despite having persistent or recurrent social or interpersonal problems caused or exacerbated by the effects of alcohol.
7	Important social, occupational, or recreational activities are given up or reduced because of alcohol use.
8	Recurrent alcohol use in situations in which it is physically hazardous.
9	Alcohol use is continued despite knowledge of having a persistent or recurrent physical or psychological problem that is likely to have been caused or exacerbated by alcohol.
10	Tolerance as defined by either the following: (a) A need for markedly increased amounts of alcohol to achieve intoxication or desired effects (b) A markedly diminished effects with continued use of the same amount of alcohol.
11	Withdrawal, as manifested by either of the following: (a) The characteristic withdrawal syndrome for alcohol (b) Alcohol (or a closely related substance, such as a benzodiazepine) is taken to relieve or avoid withdrawal symptoms.
	The presence of at least 2 of these symptoms indicates **Alcohol Use Disorder (AUD)**. The severity of the AUD is defined as: **Mild**: The presence of 2 or 3 symptoms **Moderate**: The presence of 4 to 5 symptoms **Severe**: The presence of 6 or more symptoms

A unit in the UK equates to:

- A single small shot (25 mLs) of spirits ABV 40%
- Beer 250 mLs ABV 4%
- Wine 76 mLs 13%

To work out how many units there are in any drink multiply the total volume of the drink in mLs by its ABV (measured as a percentage) dividing the result by 1000:

Strength (ABV) × volume (mL) ÷ 1000 = units.
So in a pint (568 mL) of lager (ABV 5.2%):
5.2 (%) × 568 (mL) ÷ 1000 = 2.95 units

In the United States, one 'standard' drink contains 14 g of pure alcohol; in Australia a standard drink is any drink containing 10 g of alcohol [159]. Research from the European Union shows a variation between 8–20 g in what is described as a standard drink [160].

WIT.0043.0086.0450

Most people who have alcohol in the body have drunk it, although it can be absorbed into the systemic circulation through the lungs (blood alcohol concentrations of up to 50 mg/100 mL have been achieved after breathing alcohol/air mixtures for several hours) [161]. Little or no alcohol is absorbed through the intact skin of adults.

Once ingested, alcohol is subsequently absorbed into the body by a process of passive diffusion that occurs across the mucosal surfaces of the gastrointestinal tract. As liquids pass quickly through the mouth and esophagus, little absorption takes place until alcohol has reached the stomach. The rate of absorption is maximal in the duodenum, because its mucosa is thinner and blood supply more abundant than that of the stomach. Accordingly, any condition that delivers drink into the small intestine more quickly than normal, such as gastrectomy, will lead to more rapid absorption and an earlier, higher peak blood alcohol level.

As soon as alcohol enters the bloodstream, mechanisms for its removal come into action. Some 5–10% of the total amount absorbed is excreted unchanged in breath, urine, and sweat [162], an important factor that allows the estimation of blood alcohol concentrations from the levels in urine and breath. The remaining 90–95% of alcohol is oxidized in the liver by alcohol dehydrogenase to form acetaldehyde, and this is further metabolized to acetate (acetic acid). As alcohol dehydrogenase becomes saturated at relatively low alcohol concentrations, it soon reaches its maximum working rate, and alcohol elimination proceeds at this constant rate [163].

The rate of absorption is very much faster than the rate of elimination, and this fact gives rise to the characteristic blood–alcohol curve, as described by several researchers (Fig. 12.1) [164, 165]. Generally speaking, the peak blood alcohol concentration is reached 30–60 min after drinking, although the range may be anything from 20 min to 3 h. However, the peak blood alcohol concentration, the time taken to reach the peak, the area under the blood–alcohol curve, and the time taken to reach a zero blood alcohol level vary from person to person and within the same person over time [166]. Indeed, a large number of factors can influence the kinetics of alcohol.

Sex and Weight

Alcohol is highly hydrophilic, so once it enters the systemic circulation it is distributed evenly throughout total body water (V_d or the volume of distribution). In general, the larger the person the larger the V_d, so that if two different sized males drink the same quantity of alcohol, a higher peak concentration will be reached in the lighter of the two because he will have a smaller V_d for the alcohol to distribute itself throughout. Similarly, because women have more body fat compared with men, and fat contains no water, higher peak alcohol levels are achieved in women than in men of the same weight. The V_d of alcohol for adult males has been shown to be about 0.70, compared with 0.60 for adult females [162].

WIT.0043.0086.0451

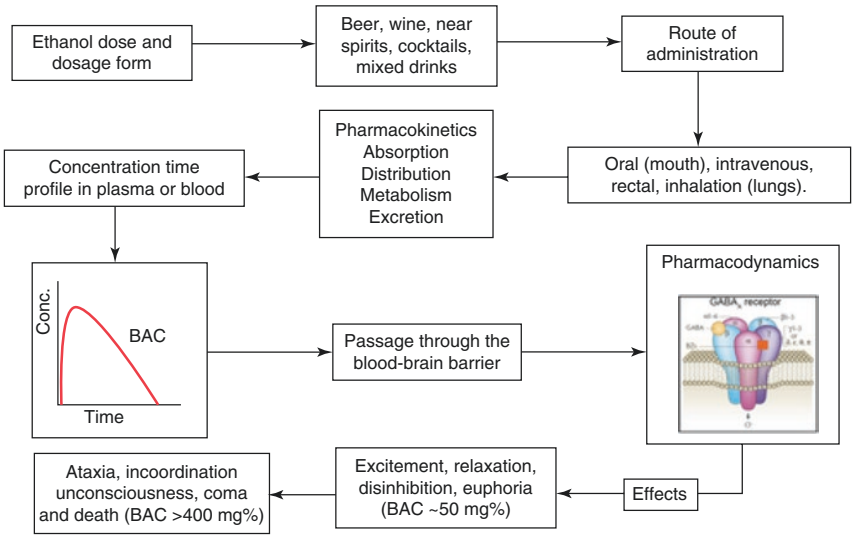

Fig. 12.1 From: Jones AW Alcohol, its absorption, distribution, metabolism, and excretion in the body and pharmacokinetic calculation. WIREs Forensic Sci 2019;e1340

Duration of Drinking

If a volume of alcohol is consumed over a prolonged period, it may be eliminated almost as quickly as it is absorbed, giving rise to a much lower peak alcohol concentration.

Nature of the Drink Consumed

The rate of alcohol absorption increases with the concentration of the ingested solution up until levels of between 10% and 20%, at which point absorption is maximal. Because alcohol is absorbed by passive diffusion, the rate of absorption is slower with drinks of lesser strength because of a lower concentration gradient. Furthermore, the larger volumes involved may also delay gastric emptying and further slowdown absorption. By contrast, when the alcohol concentration of drinks exceeds 20% the alcohol irritates the gastric mucosa and pyloric sphincter, causing increased secretion of mucus and delayed gastric emptying, thus slowing down absorption. Carbonation of drinks may also increase the rate of absorption of alcohol although this effect does seem to be variable [167].

Food in the Stomach

Studies have shown that eating a full meal before drinking can reduce the peak alcohol level by an average of 9–23% [162, 168–170]. The presence of food in the

WIT.0043.0086.0452

stomach reduces the rate of gastric emptying, dilutes the alcohol that enters the stomach, and limits the contact between the alcohol and the gastric mucosa. Alcohol absorption is slowed for all these reasons.

Physiologic Factors and Genetic Variation

Factors such as stomach wall permeability, blood supply to the alimentary tract, and the rate of gastric emptying will vary from person to person, and from time to time in the same person. All of these will have a bearing on the shape of the blood–alcohol curve.

Drugs

The interaction between alcohol and drugs, either prescribed or illicit, is important because so many detained persons take other drugs in conjunction with alcohol. Generally speaking, the most important interactions involve drugs altering the way a subject responds to a given amount of alcohol in the blood, for example, because the drug has CNS depressant effects that add to those of alcohol. However, a number of drugs may influence the rate of alcohol absorption by virtue of their effect on the rate of gastric emptying (Table 12.14).

Rate of Elimination

The rate of elimination of alcohol has been determined experimentally. Reported values range from about 10 mg/100 mL of blood per hour (mg/dL/h) to 25 mg/dL/h,

Table 12.14 Drugs that affect the rate of stomach emptying and so influence the rate of alcohol absorption

Drugs that slow gastric emptying
Drugs with anticholinergic actions, such as
Atropine
Chlorpromazine
Tricyclic antidepressants
Drugs with an adrenergic action, such as
Amphetamines
Drugs with an opioid action, such as
Antidiarrheal medicines
Codeine and dihydrocodeine
Diamorphine (heroin)
Methadone
Dextropropoxyphene (in co-proxamol)
Drugs that hasten stomach emptying, such as
Metoclopramide
Cisapride
Erythromycin

Adapted from Ferner [161]

WIT.0043.0086.0453

with an average of 15–18.6 mg/dL/h [163, 171] (approximately equivalent to the elimination of 1 unit of alcohol per hour in a 70-kg male). Habituation to alcohol is the single most important factor affecting the rate of elimination. One recent study reported the rate of ethanol disappearance in 22 alcoholics as ranging from 13 to 36 mg/dL/h, with an average of 22 mg/dL/h [172]. The increased rate of elimination is thought to be because chronic alcoholics have facilitated liver enzyme systems.

Effects of Alcohol

Alcohol acts as a CNS depressant, which in small doses interferes with cortical function, but which in larger doses may depress medullary processes. The apparent stimulatory effects of alcohol occur because it acts first on the so-called higher centers of the brain that govern inhibition. The signs of intoxication are given in Table 12.15.

While there is general agreement on the sequence of clinical effects caused by drinking alcohol, the blood alcohol concentrations at which these effects occur vary considerably in different subjects. The difference in susceptibility is most marked between habituated and non-habituated drinkers, but tolerance to the effects remains very variable even within these broad categories [173, 174]. Table 12.16 provides a guide to the general effects. It should be noted that the effects are more pronounced when blood alcohol levels are rising than when falling. This is known as the Mellanby effect and is thought to be due to an acute tolerance to alcohol that develops during intoxication [175]. Some specific effects are discussed below.

Table 12.15 Signs of alcohol intoxication

• Disinhibition/labile effect;
• Sedation;
• Concentration/attention/memory difficulties;
• Smell of alcoholic liquor;
• Tachycardia;
• Hypertension;
• Flushing;
• Nystagmus;
• Pupil size—may be normal or dilated;
• Sluggish pupillary reaction to light;
• Poor co-ordination;
• Romberg's positive;
• Ataxia.
Severe intoxication/overdose
• Alteration in mental state;
• Hypoglycaemia;
• Respiratory depression;
• CNS depression (coma with pin-point pupils);
• Depressed or absent corneal, gag or deep tendon reflexes;
• CVS depression.

WIT.0043.0086.0454

Table 12.16 Sequence of central nervous depressant effects of alcohol

Stage of influence	Blood alcohol concentration (mg/100 mL)	Clinical effect
Sobriety	10–50	Often no obvious effect
		May feel "relaxed"
Euphoria	30–120	Mild euphoria with increased talkativeness
		Decreased inhibitions
		Increased self-confidence
		Impaired fine motor skills
Excitement	90–200	Emotional instability
		Poor sensory perception
		Impaired memory and comprehension
		Incoordination and loss of balance
Drunkenness	150–300	Disorientation, mental confusion
		Disturbances of vision (e.g., diplopia)
		Decreased pain sense
		Increased incoordination with staggering gait
		Slurred speech
Stupor	250–400	General inertia approaching paralysis
		Marked lack of response to stimuli
		Inability to stand or walk
		Vomiting, incontinence of urine and feces
Coma	350–500	Coma and anesthesia
		Depressed or absent reflexes
		Cardiovascular and respiratory depression
		Possible death
Death	Over 450	Death from respiratory depression

Nystagmus

As the eye is effectively part of the CNS, it is one of the easiest parts of the body to examine in order to detect the effects of alcohol; the most extensively studied ocular effect of alcohol intoxication is nystagmus. Alcohol can cause nystagmus through at least two mechanisms. By acting on the vestibular system, it can cause positional alcohol nystagmus (PAN) [176], detected when the patient is lying supine with the head turned to either the left or right. Horizontal gaze nystagmus (HGN) results from the inhibition of the smooth pursuit system and the impaired ability to maintain eccentric gaze [177] brought about by alcohol's effect on ocular movements via neural mechanisms [178].

PAN occurs in two stages [179]. The first stage, PAN I, is associated with acute elevation of blood alcohol, tending to occur about 30 min after alcohol ingestion. In PAN I the fast phase of nystagmus is in the direction toward which the head is turned. PAN II normally occurs at about 5–6 h after drinking and is characterized by nystagmus in the opposite direction to that seen in PAN I.

WIT.0043.0086.0455

HGN is a jerky eye movement noted when gaze is directed to one side. The fast phase of HGN is in the direction of gaze, and it becomes intensified at a more eccentric gaze position [178]. Although HGN can be seen in normal individuals at extreme lateral gaze [180], when detected at lesser deviations it is considered pathologic. An angle of onset of 40° or less from the midline has been found to be a sensitive indicator of a blood alcohol level in excess of 100 mg/100 mL [178]. While some authors have maintained that blood alcohol levels of over 80 mg/100 mL are consistently associated with HGN [181], others have found that it is absent in just under 40% of drivers with an average blood alcohol of 120 mg/100 mL (range 9–218 mg/100 mL) [182]. As HGN may be noted in a number of pathologic conditions including the ingestion of sedative and tranquilizing drugs [183], its presence should not be taken as proof of alcohol intoxication, especially as evidence in cases of driving while intoxicated (DWI) [184]. It is perhaps for these reasons that the Kansas Supreme Court, when assessing the admissibility of HGN evidence in drink driving prosecutions, decided that "the reliability of HGN evidence is not currently a settled proposition in the scientific community" [185].

Pupillary Changes

In the early stages of alcoholic intoxication, the pupils are said to dilate, often becoming pinpoint as the level of intoxication advances, particularly when the state of coma is reached [186]. However, some commentators report the pupils as being normal-sized in alcohol intoxication [187], with current advice favoring the view that pupil size may be normal or dilated.

Alcohol may slow the pupillary response to light, such an effect being one of the more reliable eye signs of intoxication albeit a difficult one to detect clinically.

Slurred Speech

Speech production is a complex motor activity. As it requires a high degree of coordination, it can be a sensitive index of alcohol intoxication [188]. Reliable changes in speech are produced at blood alcohol levels above 100 mg/100 mL [189], although the effects of lower blood alcohol levels have been variable.

Cardiovascular Effects

Moderate doses of alcohol cause a slight increase in blood pressure and pulse ate, [190, 191]. However, the most prominent effect with higher doses is a depression of cardiovascular functions. This depression is probably a combination of central effects and direct depression of the myocardium [175].

Metabolic Effects

HCPs need to be aware that severe hypoglycemia may accompany alcohol intoxication because of inhibition of gluconeogenesis. Alcohol-induced hypoglycemia, which develops within 6–36 h of heavy drinking, typically occurs in an undernourished individual or one who has not eaten for the previous 24 h. The usual features of hypoglycemia, such as flushing, sweating, and tachycardia, are often absent, and the person may present in coma.

Death from Alcohol Poisoning

Alcohol intoxication may result in death due to respiratory or circulatory failure or as a result of aspiration of stomach contents in the absence of a gag reflex. Levels of blood alcohol above 500 mg/100 mL are considered to be "probably fatal" [192], although survival at much higher concentrations is now well documented. In 1982, for example, the case of a 24-year-old woman with a blood alcohol level of 1510 mg/100 mL was reported. She had gone to the hospital complaining of abdominal pain and was noted to be conscious but slightly confused. Two days later her pain had eased, her blood—alcohol level fallen, and she was able to leave the hospital and return home [193].

Death associated with blood alcohol levels below 350 mg/100 mL suggests that other complicating factors are present. Most commonly this will be an interaction between alcohol and some other drug that has also been ingested.

Diagnosis of Intoxication

The terms alcohol intoxication and drunkenness are often used interchangeably. However, a distinction between these terms is justified as people may exhibit behavioral changes associated with drunkenness when they believe they have consumed alcohol but actually have not [194] (Table 12.17).

Alcohol Dependence

Alcohol use disorder is a major risk factor for serious health, social, and economic problems [196]. Early identification of those who are dependent on alcohol increases the possibility of successful treatment [197] and brief intervention by the HCP seems both feasible and acceptable [198].

It is essential that custody staff ensure that those who are identified on risk assessment with an alcohol problem and/or are suspected of being dependent on alcohol should call a HCP to fully assess the detainee, and whether in view of the proposed length of detention, early treatment is required to prevent the major complications of withdrawal (see below).

WIT.0043.0086.0457

Table 12.17 Differential Diagnosis of Alcohol Intoxication [195]

Differential diagnosis	Clinical marker(s)
Other Intoxicants	
Drugs of abuse Cocaine/Amphetamines-type stimulants Opiates Prescribed medication: benzodiazepines, anti-psychotic medications	Personal history of use Information from police (National computer database) Drug possession/drug paraphernalia identified during police search (e.g. citric acid) Disproportionate mental stimulation Injection marks, excessive sedation Medications found/prescriptions, hospital appointment cards
Infections (Sepsis)	History/Examination for source of infection Pyrexia Meningism
Head injury	History of head injury, particularly at time of arrest Visible head injury Localising neurological signs
Metabolic causes Hypoglcaemia Hyperglycaemia/diabetic ketosis	MEDIC ALERT bracelets Blood glucose measurement Blood glucose measurement/urinalysis for ketouria
Other electrolyte disturbance	Diuretic use, other comorbid conditions (cancer, heart failure etc.)
Hepatic encephalopathy	Signs of chronic liver disease, ascites
Other	
Seizures/post-ictal states Acute psychiatric conditions Hypoxia/hypercapnia	Confusion/disorientation Abnormal mental state examination Pulse oximetry

However, obtaining accurate and reliable information about a person's drinking habits can be extremely difficult. The use of an alcohol screening questionnaire is essential in identifying alcohol problems [199]. The Alcohol Use Disorders Identification Test (AUDIT) identifies persons whose alcohol consumption has become harmful or hazardous to health [200] and is probably the best screening instrument in this environment [201]. This can be used in combination with the Severity of Alcohol Dependence Questionnaire (SADQ) [202].

Alcohol Withdrawal

All HCPs working in the custody environment should be skilled in the assessment of detainees with AUD, including alcohol withdrawal. Detainees with marked alcohol dependence may develop withdrawal symptoms before the alcohol level is zero. Alcohol withdrawal symptoms and signs include: agitation, tremor, sweating, fever, tachycardia and hypertension. Complications of severe withdrawal include seizures, hallucinations, confusion, disorientation, aggressive behaviours and delirium tremens. The use of a tool such as Clinical Institute Withdrawal Assessment for Alcohol (CIWA) [203] is recommended. The severity of the symptoms depends

WIT.0043.0086.0458

mainly on the amount and duration of alcohol intake, although other factors, such as concurrent withdrawal from other drugs, such as benzodiazepines, may contribute to the clinical picture. Detainees at high risk, with a past history of severe withdrawal with seizures or previous delirium tremens should be transferred to hospital. Treatment should be given using a long acting benzodiazepine in custody, such as diazepam or chlordiazepoxide. A symptom-triggered regimen for drug treatment for people in acute alcohol withdrawal should only be used in hospital or in other settings where 24-h assessment and monitoring are available [204].

Alcohol Withdrawal Delirium

The essential diagnostic feature of this disorder is a delirium that develops after recent cessation of or reduction in alcohol consumption. Traditionally referred to as delirium tremens, this withdrawal state typically begins 72–96 h after the last drink, so it is uncommon within the normal span of detention in police custody. However it may occur earlier (after 24 h). The delirium is characterized by impaired attention and memory, disorganized thinking, heightened suggestibility, disorientation, reduced level of consciousness, perceptual disturbances, and agitation. Vivid, and often terrifying, hallucinations may occur. Usually these are visual, but other sensory modalities (e.g. auditory or tactile) may be involved. The disorder usually coexists with other features of alcohol withdrawal, for example, autonomic hyperactivity, which is usually severe. Alcohol withdrawal delirium is a medical emergency with a mortality rate of about 5%. Once diagnosed, the detained person with delirium requires urgent hospitalization.

Withdrawal Seizures

Seizures are typically single and generalized. They tend to occur between 6 and 48 h after the last drink and while they are not life threatening, their importance lies in the fact that about one third of those with seizures will go on to develop alcohol withdrawal delirium.

Alcoholic Hallucinosis

The essential features are auditory or visual hallucinations, which develop either during or after a period of heavy alcohol consumption.

Cardiac Arrhythmias

The frequency of tachyarrhythmias in alcohol withdrawal is high, probably because of high adrenergic nervous system activity. Sudden deaths in alcohol withdrawal are

WIT.0043.0086.0459

most likely due to such dysrhythmias. Adequate sedation will play a part in preventing such unwanted occurrences happening in police custody, although those with severe alcohol withdrawal are best admitted to the hospital, where they can be placed on a cardiac monitor.

Wernicke's Encephalopathy and Korsakoff's Psychosis

Wernicke's encephalopathy is a medical emergency which may be precipitated by alcohol withdrawal, or intercurrent illness, such as sepsis. Features include disturbance of consciousness (ranging from mild confusion to coma), double vision, ophthalmoplegia, nystagmus, and ataxia. The disorder is due to a poor intake, or absorption of, thiamine and has a high mortality (up to 20% in the acute stage). Korsakoff's psychosis often emerges as a chronic disorder after an episode of Wernicke's encephalopathy. This usually presents as impairment of short-term memory with inability to learn new information and compensatory confabulation. Korsakoff's psychosis probably represents irreversible brain damage secondary to the combined toxicity of alcohol and metabolic derangement due to thiamine deficiency.

Memory Problems Associated with Alcohol

'Blackouts' associated with use of alcohol suggests transient memory loss which may be induced by intoxication but there is no loss of consciousness. There is a significant association between the BAC and the level of amnesia reported. As the BAC increases the likelihood of complete memory loss (blackout) or fragmentary memory loss (grayout) increased [205].

Detainees who have severe AUD may have a form of dementia with mild to moderate impairment of short- and long -term memory.

Key Points

- The management of detainees with substance use disorders can be challenging in the custody environment. HCPs should be aware of drug trends in their area of practice.
- Early assessment and prompt treatment of alcohol dependent detainees is essential to prevent the complications of withdrawal.
- If drug facilitated crime, including and drug facilitated sexual assault, is suspected the appropriate forensic samples should be taken.
- Detainees are entitled to have their prescribed medication continued in custody as long as it is clinically safe to do so. This includes opiate substitution treatment such as methadone or buprenorphine.

Self-Assessment Exercises

1. List the symptoms and signs of stimulant intoxication?
2. How would you treat gamma-hydoxybutyrate (GHB) withdrawal in custody?
3. What is the half-life of methadone? How does this inform the need for treatment?
4. What is Korsakoff's psychosis and how should it be treated?

Acknowledgments Acknowledgment to Dr. Guy Norfolk not involved in this revised edition.

Deaths in Police Custody

13

Richard T. Shepherd

Learning Objectives

Outline the main causes of death in police custody.
Describe acute behavioral disturbance and excited delirium.
Demonstrate the ability to verify life extinct.
Understand the requirement of a death in custody investigation.

Introduction

Healthcare Professionals (HCP) will, in all probability, have to deal with a death in police custody at some point in their career. This chapter aims to provide a broad basis for the understanding of the disease processes, the mechanisms that may lead to death, and also to outline the current thinking behind deaths associated with restraint.

Definition

When considering any death associated with detention by officials of a state, caused by whatever means, each state will define, according to their own legal system, the situations that are categorized as being "in custody" [1]. The worldwide variation in these definitions continues to cause considerable confusion in any discussion of this subject. For the purposes of this chapter "in custody" relates to any individual who is either under arrest or otherwise under police control and, while similar deaths may occur in prison, on psychiatric wards or in other situations where people are detained against their will, it is the deaths specifically associated with police detention that will form the basis for the discussion here.

WIT.0043.0086.0471

Having defined the broad parameters of the subject, it is important to distinguish between the different types of custodial deaths since it is deaths that are related to direct police actions (acts of commission) that seem to cause the greatest concern to the family, the public and the press. It is also important to remember that police involvement in the detention of individuals extends beyond direct physical contact and includes a "duty of care" to that individual and any "lack of care "in this situation may be termed "act of omission". Lack of police action, or "care", has also been responsible for deaths in custody. These acts are considerably harder to define and sometimes result from the police being placed in, or assuming, a role of caring (for instance, in states of alcoholic intoxication or acute psychiatric conditions) that are beyond their competence or which they are not equipped or trained to fulfil.

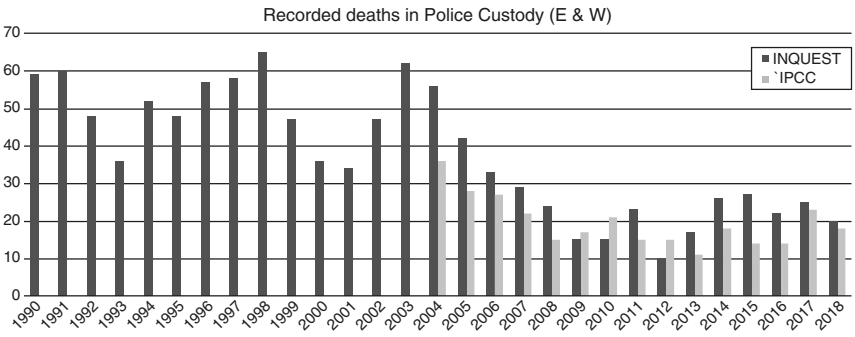
Police involvement with an individual can also include those who are being pursued by the police either on foot or by vehicle, those who have been stopped and are being questioned outside the environment of a police station, and those who have become unwell through natural causes while either in contact with, or in custody, of the police.

The definitions of "death in custody" are therefore wide, and attempts at setting definitions that cover all aspects of such deaths are fraught with difficulty. Any definition will have to cover a multitude of variable factors, in various circumstances and with a wide variety of individuals [2, 3]. The crucial point is that, in a civilized society, the police owe a duty of care to each and every member of the public with whom they have contact and it is essential that every police officer, whether acting or reacting to events, understands and is aware of the welfare of the individual or individuals with whom he or she is dealing.

Statistics

The lack of a standard international definition of "death in custody" means that the simple comparison of the published raw data from different countries is of limited value. The number of deaths in police custody in England and Wales from 2004 to 2018 recorded by Dame Angiolini's report [2], INQUEST [4], and the Independent Office of Police Conduct (IOPC), previously known as the Independent Police Complaints Commission (IPCC) [5], shows considerable variation year on year, and also between the different data sets (Graph 13.1). This data must be treated with considerable care since any changes in the death rates may not be the result of changes in the policy and practice of care for detainees but other, undetermined, factors such as increases or reductions in arrest rates over the period as a result of changes in local policing procedures or central governmental policy.

The National Deaths in Custody Program (NDICP) has monitored deaths occurring in prison, police custody and youth detention in Australia since 1980. The Australian Institute of Criminology (AIC) has coordinated this program since its establishment in 1992 following a recommendation of the Royal Commission into Aboriginal Deaths in Custody (RCIADIC). The most recent figures from 2016 to



Graph 13.1 Deaths in police custody in England & Wales

2017 show that 17 deaths occurred in police custody and custody-related operations. Most deaths in police custody in 2016–2017 resulted from external trauma injuries and gunshot wounds (n = 5 each); four were self-inflicted, four were the result of a justifiable homicide, four were accidental, three resulted from natural causes, and two had an 'other' or unknown manner of death [6].

By comparison, and looking more closely at one published set of statistics, those from the IOPC, investigating deaths in police custody in England and Wales in 2017/2018, fatalities were noted in the following categories [7]:

- 29 road traffic fatalities
- 4 fatal shootings
- 23 deaths in or following police custody
- 57 apparent suicides following police custody
- 170 other deaths following police contact that were subject to an independent investigation

It is concerning that the number of deaths in, or following, police custody, has increased to 23 which is the highest figure recorded in 10 years. From 2004/2005 to 2008/2009, there was a year-on-year reduction in the number of deaths in or following police custody from 36 deaths in 2004/2005 to 15 deaths in 2008/2009. Over the next 2 years, the number of deaths in custody increased to 21 in 2010/2011, before falling back to 15 in 2011/2012 and 2012/2013. There was a further reduction, to 11, in 2013/2014. In 2014/2015, the number rose again to 18 and deaths following apparent suicide rose, although this increase is in part the result of improved identification of cases.

The Home Secretary (UK) in July 2015 announced that an independent review into Deaths in Custody was to be carried out by Dame Elish Angiolini QC [2]. The report of this review, published in 2017, made 110 recommendations on a variety of

Table 13.1 Themes in causes of death in police custody

• Drugs, alcohol, mental health—co-morbidities
• Missed drug swallowing
• Intoxication—actual level and masking other medical issues (and with time withdrawal)
• Failure to perform an adequate risk assessment—risk factor in itself
• Failure around the checks and rousing by custody staff
• Consider restraint
• Written and verbal handover to custody staff by HCPs (communication)

areas including: restraint, custody environment, health and wellbeing, funding for families and family support, communications, investigations, coroners and inquests, accountability, training, learning, statistics and research.

Natural causes have been the most common known cause of deaths in police custody in England and Wales between 2004/2005 and 2014/2015, accounting for 51% of causes of death in this period. Drugs and/or alcohol also featured as in the causes of death in around half of deaths (49%), and an even higher proportion of those who died had an association with drugs or alcohol (82%). A significant number of themes have been identified (Table 13.1).

Investigation of Deaths in Custody

Legal Framework

In England and Wales the death of any individual who is detained in prison or under the Mental Health Act must be reported to the Coroner, however if the individual is detained by a police officer in a public place, a police vehicle or in a custody suite then there is no obligation to report the death to HM Coroner although in practice all such cases are referred. The Home Office has recommended [8] that all deaths falling into even the widest definition of "in custody" should be subject to Coronial Inquest [9] and hence a full inquiry into the facts and a full postmortem examination should be performed. In the UK Article 2 (The Right to Life) of the European Convention of Human Rights is invoked which accepts that all deaths occurring in custody should be fully investigated and considered by the legal system. However, not every country will follow this, and some local variations can and do occur outside the European Union, this is particularly so in the USA.

Protocol

No standard or agreed protocol has been devised for the postmortem examination of these deaths and, as a result, variation in the extent of the examination and the subsequently reported details is to be expected. A general Code of Practice and

WIT.0043.0086.0474

performance standards for Forensic Pathology [10] has been published and any pathologist considering performing an examination of a death in custody would be well advised to consider that document with care before proceeding. Despite this, the differences in the procedures and the number and type of the specialist tests performed inevitably results in considerable variation in the pathological detail available as a basis for establishing the cause of death and hence available for presentation at any subsequent inquest or criminal proceeding. The absence of a defined protocol hinders considerably the analysis of the results of these examinations and makes even the most simple comparisons unreliable. There is always a need for a properly established academic study of all of these deaths, such as that performed by Lindon and Roe [1] in 2014 for the UK government. As a joint venture by Department of Health, Department of Justice and the Home Office, the Independent Advisory Panel on Deaths in Custody was constituted to inform and advise the joint Ministerial Board on Deaths in Custody [11].

In the UK, the IPCC was replaced by the IOPC in January 2018. The IOPC continues to have a major role in the management of the investigations of all deaths in custody and it also investigates many of the more serious complaints, including allegations of misconduct against the police in England and Wales. Other jurisdictions will have similar investigative organizations: The Police Ombudsman of Northern Ireland (PONI) investigates deaths in custody (https://www.policeombudsman.org/Home). In Scotland the role of the Police Investigations and Review Commissioner (PIRC) was introduced in 2013 when the police service of Scotland was established (https://pirc.scot/about-us/).

Terminology

In addition to the lack of reproducibility of the postmortem examinations, the terminology used by the pathologists to define the cause of death, particularly in the form required for the registration of the death, may often be idiosyncratic, and similar disease processes may be denoted by different pathologists using many different phrases. For example, damage to the heart muscle caused by narrowing of the coronary arteries by atheroma may be termed “Ischemic Heart Disease” or it may be called “Myocardial Ischemia due to Coronary Atheroma” or even rarely by the “lay” terminology “Heart Attack” [10]. This marked variation in terminology may often lead to confusion, particularly among lay people, attempting to understand the cause and the manner of death. Much research [3, 12] has been produced based upon such lay assessments of the pathological features of a death and this has, at times, resulted in increased confusion rather than clarification of the issues involved.

If the issues regarding the definition of “in custody”, the variation in the postmortem examinations, the production of postmortem reports, and the analysis of subsequent specialist tests, all raise problems within a single country, then the consideration of these deaths internationally produces almost insuperable conflicts of medical terminology and judicial systems.

WIT.0043.0086.0475

Deaths Related to the Phases of the Police Custodial Process

In an attempt to add some clarity to the situation, it is possible to state that whatever national definition of "in custody" is used, a number of phases of the custodial process can be identified and the types of deaths which occur during these different phases can be analyzed. Clearly a death, either sudden or delayed, may occur for many different reasons even in the absence of police but since it is the involvement of police that is the *sine qua non* of "in custody" deaths, the first phase must be considered to be the presence of police officers at the scene. Subsequently, an arrest may be made with or without the use of restraint techniques and the prisoner will then be transported to a police station.

This transport will most commonly involve a period within a police vehicle which may be a car, a van with seating or some other vehicle. Many factors may determine the type of transport used and the possible positions of the individual with the vehicle. Arrival at the police station will be followed by various assessments initially by non-medical personnel and decisions will be made regarding detention. Healthcare professionals (HCPs) may become involved, immediately or later, in the decision making process regarding fitness of the individual to be detained.

Detention in a police station will be followed by a period, or periods, of interview interspersed with periods of time incarcerated, usually alone, within a cell. Following interview the individual may be released with no further action/under investigation, they may be charged and then released or charged and detained to appear before a court. It is at this point that custody moves from the Police to other authorities, usually to the prison service.

When considering the types of death that can occur during each of these phases, six main groups can be identified based on the reported causes of death. The groups are:

- Natural deaths
- Deaths associated with accidental trauma
- Deaths related directly to the use of alcohol
- Deaths related to the use of other drugs
- Deaths associated with self-inflicted injury
- Deaths associated with injuries deliberately inflicted by a third party

It is clear that different factors may lead directly to, or play a major part in, the death of an individual while in custody and that different factors will play their part at different phases in the period of custody (see Table 13.2).

Acute alcohol intoxication or the deleterious effects of drugs are, in most cases, likely to have a decreasing effect with time as they are metabolized or excreted from the individual's body. They are therefore most likely to cause death in the post arrest and early detention phases and it is important to note that their effects will be least visible to those with the "duty of care" while the individual is out of sight, detained within a cell—particularly if they are alone within that cell. Similarly the effects of

WIT.0043.0086.0476

Table 13.2 Expected types of deaths in different phases of custody

	Natural	Accidental trauma	Alcohol	Drug	Self-inflicted	Deliberately inflicted
Pre-arrest	++	+++	++	++	±	±
Arrest	++	+++	++	++	±	+++
Detention	+	+	+++	+++	++	++
Interview	+	+	++	++	+++	+
Charge	+	+	–	–	+++	±

trauma, whether accidentally or deliberately inflicted, are most likely to become apparent in the early phases of detention and it would only be on rare occasions that the effects of such trauma would result in fatalities at a later stage although this has occurred on several occasions in particular with head injuries [13]. Conversely death resulting from self-inflicted injuries are unlikely to occur in the pre-arrest and the arrest phases of detention but can and do occur when the individual is placed in a cell and is not under immediate and constant supervision. Cell design has improved notably with the removal of potential ligature points along with the increasing use of monitoring by CCTV, but unless the detainee is constantly supervised opportunities may still arise to self-harm.

Deaths from natural causes on the other hand can occur at almost any time during the period of arrest and detention. It is possible that the stress (whether emotional or physical or both) associated with the initial phases of arrest and with the subsequent, more emotionally stressful phases during detention are likely to precipitate the death of the susceptible individuals through the effects of sympathetic stimulation and the release of adrenalin. Deaths from natural causes should be reduced by the clinical assessment of this vulnerable group of patients by competent HCPs with the appropriate knowledge, skills and experience. Custody staff must also ensure proper supervision of detainees from the time of their initial arrest and throughout the period of detention (see Chap. 9).

It is, however, quite clear that the deaths described in many reports are not "pure" i.e. they are not attributable to any one single category. Individuals with heart disease may also be under the influence of alcohol; individuals under the influence of alcohol or drugs may also have suffered trauma, either accidental or deliberate, prior to or during their detention. In determining the cause of death it can therefore be extremely difficult to give weight to each of the factors that could be identified during the period of detention. There is clearly great need for early assessment and accurate diagnosis of natural disease (physical or psychiatric), of alcohol or drug intoxication or withdrawal, and for the identification, documentation, and treatment of all types of trauma.

The removal of an individual's freedom places upon the police a duty of care to that individual and it is only by the active assessment of each and every person entering police custody and the continuing care of that individual that the number of deaths in custody can be reduced.

WIT.0043.0086.0477

Causes of Death

Natural Causes

Apart from a few unusual cases, deaths due to natural causes while in police custody fall into the groups of disease processes that are commonly associated with sudden natural death in the community.

Cardiovascular Disease

The most common cause of death in the community and of sudden death in particular, is cardiac disease, and within this group those deaths recorded as being due to ischemic heart disease or coronary atheroma are the most common. The exact definitions and criteria for the pathological diagnosis of significant ischemic heart disease [14] are not within the scope of this chapter. While there is a clear increase in the incidence of this cause of death with age [15], it is important to remember that a small percentage of people in the younger age groups, most commonly those with hypercholesterolemia and hyperlipidemia, may also have significant coronary artery disease and since it is the younger age groups that are more likely to be arrested by the police these few individuals may assume great significance.

The significance of coronary atheroma is that individuals with this disease are particularly prone to the development of dysrhythmias during periods of stress when the adrenaline-induced tachycardia results in a decreased ability to perfuse areas of the myocardium during diastole which may result in the development of ischemic ectopic electrical foci. Deaths may be preceded by the development of classical cardiac chest pain or it may present with sudden collapse and death without prior warning.

Individuals suffering from significant myocardial hypertrophy due to chronic hypertension are also at greater risk during periods of stress. Once again it is the older age groups that are most commonly affected by essential hypertension which may also render these individuals susceptible to focal lack of myocardial perfusion during periods of tachycardia. In addition to these two disease processes, there are also the much rarer diseases or syndromes that may cause sudden death which are possibly more significant in the context of "deaths in custody" since some of them tend to affect younger age groups in particular. Congenital valvular disease (e.g. floppy mitral valve disease) and congenital myocardial disease (e.g. the cardiomyopathies) may both render an individual more susceptible to sudden cardiac death and, as with ischemic or hypertensive heart disease, sudden death is more likely when the sympathetic stimulation which is associated with stress, (emotional and/or physical) has resulted in tachycardia.

Genetic research has now identified a genetic basis for many other sudden cardiac deaths in the younger age groups. These genetically mediated disease processes (for example, the prolonged QT syndrome) are often known by the generic term "channelopathies" and can sometimes be diagnosed in life by ECG, however

WIT.0043.0086.0478

after death their presence and hence their possible relationship to the sudden death, can be inferred only from the detection of specific gene defects [16]. The examination for these specific gene markers in any sudden death in police custody must now be considered essential especially in the absence of other causes of death.

Myocarditis and rheumatic heart disease are rare causes of death in young individuals although such deaths may occur without any prior indication of a disease process in individuals in police custody and elsewhere.

Other cardiovascular causes of sudden death are also, for the most part, age related. The rupture of atheromatous aortic aneurysms is a disease almost entirely confined to late middle and old age while the rarer forms of aortitis and collagen diseases of the aorta [17], which may also result in rupture, are more commonly seen in the younger age groups. The diseases that are not age related may be associated with a long history of alcohol or drug abuse and the long term effects may result in alcoholic cardiomyopathy, cocaine-related myocardial scarring, or other coronary artery or myocardial effects that can result in a sudden death even after long-term abstinence from, or just short-term lack of, alcohol or the preferred drug(s) of abuse.

Pulmonary emboli can cause sudden death or they may present as dyspnea and chest pain. It is most unusual for deep venous thrombosis of the leg veins to be present in a young active male; however, the association between some types of the combined oral contraceptive pill and the development of thromboses has been known for some time [18] and may render a small subgroup of the female population at greater risk of pulmonary emboli than the general population.

Central Nervous System

The stress associated with arrest and detention in custody may also have significant effects upon the cerebro-vascular system and may, in susceptible individuals, precipitate intracerebral hemorrhage by the rupture of congenital or acquired aneurysms or from other vascular malformations. Ruptured "berry" aneurysms will result in the development of acute subarachnoid hemorrhages. It is less likely that these intracranial hemorrhages will result in sudden death but they may result in sudden unconsciousness which leads ultimately to death. Clearly the distinction between hemorrhage due to a natural disease process and that due to trauma will need to be established and a specialist neuropathological examination will be required should death occur.

As with the heart, the possibility that an infectious process within the central nervous system is the cause of sudden collapse and death must be considered. It is however unlikely that meningitis or encephalitis will present without any prodromal symptoms. Epilepsy is unlikely to develop de novo following arrest and detention but epilepsy can, and does, lead to sudden collapse and death and a pre-existing history of epilepsy is clearly important. Any individual known to suffer from epilepsy should be monitored with the utmost care and their prescribed medication continued.

WIT.0043.0086.0479

Other forms of intracranial pathology that may lead to sudden death include tumors, both benign and malignant, and such rarities as the development of colloid cysts of the ventricular system.

Endocrine

Diabetes mellitus should raise similar concerns to those associated with epilepsy since poorly controlled diabetes may on occasions be the direct cause of sudden death. Diabetes generally, through its association with an increased incidence of arterial disease, is a major factor in the development of coronary artery disease in the younger age groups. At postmortem consideration must be given, in all cases of sudden death in a young individual but particularly when there is a history of diabetes mellitus, to the sampling of the vitreous humor in an attempt to determine the blood glucose level at the time of death. The samples need to be taken as soon after death as possible to avoid postmortem utilization of the intraocular glucose yielding erroneous results [13].

Other Causes

There are many other natural disease processes that could theoretically lead to sudden collapse and death. Amongst these is asthma, a disease that is usually unlikely to lead to sudden death if adequately treated and supervised but which may, if untreated and unsupervised and in stressful circumstances, result in the individual being found dead in their cell. Other disease processes include the development of hemoptysis, from tuberculosis or pulmonary malignancy, or hematemesis, from peptic ulceration or esophageal varices, which can be life threatening and which may, because of the bleeding, be considered to be the result of trauma rather than a natural disease process. These cases should present no problem to an experienced pathologist following a full postmortem examination.

Conclusion

The significant feature when considering possible natural causes of death of an individual in police custody is that some diseases can lead to rapid collapse and death with no prior warning in a young individual who is apparently fit and well immediately prior to the collapse. There is no method that the police can use to determine which of the individuals they encounter will be suffering from these diseases or from a genetic abnormality that may lead to electrical disturbances within the myocardium. Indeed many of these disease processes can only be diagnosed after complex medical testing following the taking of a full medical history.

The fact that many of these diseases are rare in the age group that is most likely to be detained in custody places additional burdens upon the police officers required

WIT.0043.0086.0480

to care for these individuals and also upon the HCPs required to examine and treat them in the police station. The difficulties that these cases present to the pathologist lies in the need to have an awareness of all of the possible natural causes of sudden death and the need for a careful determination, and if necessary exclusion, of all of these causes—cardiac, neurological, endocrine etc., before forming the conclusion that some other factor has resulted in death.

Accidental Trauma

It is clear that determining if trauma is the result of an accident or not, may depend on the "eye of the beholder". As an example of this it is impossible at postmortem to determine if the injuries caused following a fall from a window during arrest were the result of an accidental fall, an intended jump, or a deliberate push from that window since any points of contact with the building during the descent and the contact with the ground will result in the same injuries whatever the initial "cause". Pathologically the only features of relevance in determining the exact cause of the initiation of the descent are the identification of specific gripping, holding or other restraining injuries that could have occurred prior to the descent or the identification of marks or injuries that may or may not be present (for instance to the fingers) that could be ascribed to attempts to hold on to a window ledge etc. All of the injuries or marks found on the body will have to be correlated with witness statements both from the police and from any other parties present at the time of the fall. Often the true interpretation of many of the injuries and marks found during the postmortem will only become clear when these statements are considered.

In general terms, however, accidental trauma can be caused by many events during the course of an arrest. Falls onto the ground may occur from a height or from standing. Gripping and restraining injuries are commonly present on many areas of the body but are likely to be most common on the arms. The site and significance of the injuries present will depend on the descriptions of the events before, during and after the arrest.

It is essential that all injuries, no matter how apparently trivial, present on a detained individual are carefully documented by the HCP who examines the detainee whether at a police station or elsewhere. Contemporaneous photographs are always extremely helpful in these circumstances and all injuries should be photographed both with and without a measuring scale (see Chap. 4). The ageing of bruises is fraught with difficulties and the documentation of any observed colors and the changes of colors in bruises by the HCP can be of importance. However many factors such the nature of the light (natural, fluorescent, etc.) in which the injuries are viewed may cause significant apparent differences and in addition inter-observer variations may render simple verbal descriptions less reliable. Careful photography with the mandatory inclusion of a standard color strip in the photographs is essential if later review of color is to be if any value.

In terms of a cause of death few of the minor injuries will be relevant but they may provide an indication of the extent and degree of the force that was applied to

WIT.0043.0086.0481

effect an arrest and, as such, they can be of immense value. Injuries present in sites that are known to be of high risk, for instance around the neck, must be examined, documented and interpreted with particular care. All of the injuries need to be interpreted in the light of witness statements and can provide very useful corroborative evidence.

Alcohol and Drug Related Deaths (See Chap. 12)

Alcohol

Alcohol is one of the most commonly used drugs in the world. The small ethyl alcohol molecule can pass easily through the blood–brain barrier to the CNS where it has direct suppressant effects on the whole of the central nervous system. At low concentrations the specialized cells of the cerebral cortex are affected but as the concentration increases the depressive effects involve the higher areas of the brain resulting in increasingly disinhibited behavior. Still higher levels of alcohol result in the depressant effects involving the lower levels of brain function, including the vital cardiorespiratory centers in the midbrain and the medulla, predisposing the intoxicated individual to cardiorespiratory depression or arrest. Alcohol levels in excess of 300 mg/dL are considered to be potentially lethal although some individuals have survived, usually with medical attention, with far higher levels. Some, it must be remembered, have died with far lower levels of alcohol in their blood stream.

The effects of alcohol are however not confined to the brain, there is also marked peripheral vasodilation resulting in increased heat loss which may, on occasions, lead to hypothermia. The adverse effects of alcohol on the coronary circulation, particularly when associated with significant coronary atheroma may lead to myocardial ischemia and the development of dysrhythmias and sudden death.

Alcohol also has marked diuretic effects and when combined with the ingestion of large quantities of fluid (particularly in beer and lager drinking) this may result in electrolyte disturbances particularly hyponatremia.

The chronic effects of alcohol involve many of the internal organs; alcoholic cardiomyopathy, hepatic steatosis and cirrhosis are the most common and all can lead to sudden death.

Alcohol may also be a major factor in causing death by predisposing the individual to accidental trauma and by obscuring the effects of that trauma [13, 19]. This is particularly the case in head injuries when the changes in conscious level are attributed to the effects of alcohol rather than an identified or unidentified head injury.

Alcohol is also a gastric irritant and may precipitate vomiting when taken in excess. This, combined with the effects of decreased consciousness and the reduced laryngeal reflexes associated with intoxication, result in a significantly increased risk of aspiration of vomit into the airways and death. Such an event is unpredictable and, without constant supervision, unpreventable.

The anesthetic effects of alcohol may also result in deaths from asphyxiation. These deaths are the result of the intoxicated individual moving into, or being placed or left, in a position that impedes respiration either by occlusion of the external respiratory orifices, the internal airways (particularly the larynx), or restricts the free movement of the chest wall. These positions may result from lying face down on a bed, marked extension or flexion of the neck or lying across an edge with the head down. Deaths resulting from impairment of respiration in this manner classically result in profound asphyxial changes involving the upper body and these deaths are ascribed to postural asphyxia.

The metabolism of alcohol follows pathways that results in temporary increase of toxic chemicals including ketones (acetaldehyde, β-hydroxybutyrate etc.) in the blood. These metabolic products result in raised blood acidity and cause further disturbances in sodium/potassium, glucose and other metabolic pathways. If the natural balancing chemical buffers of the body are overcome and the blood acidity falls significantly, cardiac dysrhythmias can be produced and sudden death can occur. Postmortem analysis of the blood for β-hydroxybutyrate (BHB) is now readily available and should always be performed in all custodial deaths.

Given the speed with which an individual under the influence of alcohol can die from either the aspiration of vomit or from postural asphyxia it is very doubtful if a police station cell is the correct environment for their recovery from intoxication.

Illustrative Case *A homeless male was arrested by police for the theft of alcohol. He was unkempt and smelt of intoxicating liquor. He was slurring his speech and had an unsteady gait. The custody officer authorized his detention and on the risk assessment it was noted that the detainee said he drank alcohol every day. The detainee was placed in a cell, and as he was currently intoxicated with alcohol, he was checked and roused every half hour for four hours to ensure that his condition was improving. He was then left for a period of undisturbed sleep, though was observed hourly. Unfortunately there was a change of shift in the police station and the fact that the detainee was most likely alcohol dependent was not communicated to the incoming shift team. The detainee was found dead in the morning some 16 hours after his arrest. CCTV footage confirmed that he had seizure in the night prior to his death.*

Drugs

Drug use is now so ubiquitous in western society that any examination of a detainee by a HCP must include a very careful evaluation of drug use whether in the past or recently. The skill of the HCP will undoubtedly be stretched to the full in the evaluation of the history given and this is discussed fully in Chap. 12; much may depend on the failure to continue prescribed medication as on the failure to identify a detainee who is misusing substances who then suffers from withdrawal whilst in custody.

WIT.0043.0086.0483

In terms of deaths in custody all drug use, whether social, misuse or therapeutic, is relevant [1–4, 13, 19] and the possibility that a detainee may have used just one drug or a combination of drugs with or without alcohol prior to death must be positively excluded. A full drug screen on blood and, if available, urine is imperative. Some laboratories will also examine samples of bile and/or liver to detect evidence of previous drug abuse. At postmortem the contents of the whole bowel must be examined to determine if packets or 'wraps' of drugs have been ingested in order to prevent detection during arrest 'body swallowers' or 'body packers'.

The management of acute drug intoxication is a matter of clinical judgment but with adequate medical care it is unlikely that, except in exceptional circumstances, drug intoxication alone will to lead to sudden death in custody.

Deliberate Injuries

Baton Blows

Blows from a baton are usually easily identified in that forceful blows produce the classic "tram line" type injuries on the skin. "Tram line" injuries are typical of a blow from a linear blunt object, the areas of the skin that are most traumatized are not those at the middle of the site of contact where the skin is most evenly compressed but rather at the margins on the contact site where the stretching and distortion of the skin, and hence the damage to the underlying tissues including the blood vessels, is most pronounced. A linear object will, almost by definition, have two such margins which run parallel and a blow from such an object results in two, linear, parallel bruises hence the terminology "tram line".

Blows from a baton may also result in deeper bruising, nerve damage and fractured bones. The deeper injuries tend to reflect the use of greater force but it is not possible to correlate with any degree of certainty the amount of force needed to cause a particular injury in any one individual.

It is essential for both the HCP who examines a living victim of a blow to the head from a baton (or from any other cause) and the pathologist who performs a post mortem examination to remember that significant cerebral trauma can have been caused even in the absence of obvious external trauma or skull fractures. It would be a matter of prudence to assess with great care anyone who has received, or complains of receiving, a head injury from a baton, or from any other cause, and to consider carefully if referral to hospital for a full neurological assessment would be advisable (see Chap. 9).

Neck Holds

Pressure on and around the neck is well known to be a potentially lethal action [13]. Death can be caused following compression of the neck by any one of four mechanisms or by a combination of two or more of them.

WIT.0043.0086.0484

- Airway obstruction by direct compression of the larynx or trachea or by the pressure on the neck raising the larynx upwards and causing the superior aspect of the pharynx to be occluded by the base of the tongue. This can be achieved by pressure of a forearm across the front of the neck, sometimes called the "Choke Hold".
- Occlusion of the veins in the neck. The low pressure in the venous system and the thin yielding nature of the vein walls makes venous occlusion more easily achievable than arterial occlusion; however, the large reserve capacity of the venous system makes it unlikely that rapid death would result even if complete occlusion was achieved, unless some other factor supervened.
- Compression or occlusion of the carotid arteries. This is harder to achieve than venous occlusion due to the higher pressure in the arterial system and the thickness of the arterial walls; however, the effects of occlusion will become apparent much quicker. Saukko and Knight [13] record that occlusion of the carotid circulation for a period of 4 min or more may result in brain damage and Reay et al. [20] demonstrated significant changes in blood flow in the face of five individuals who were subjected to compression of the carotid arteries by the application of a "sleeper hold" in experimental conditions. A sleeper hold is applied when the upper arm compresses one side of the neck and the forearm the other and the larynx rests in the "V" formed by the elbow.
- The fourth mechanism by which death can occur during pressure to the neck results from stimulation of the vagus nerve by direct pressure in its course down the neck or as a result of stimulation of the carotid sinus. Vagal stimulation results in bradycardia which may progress to asystole or, in some cases, immediate asystole.

Mercy et al. [21] reviewed 20 deaths where neck holds had been applied and concluded that in 19 of these cases the application of the neck hold was associated with the death. Conversely, Kowai [22] concluded that the use of the Choke Hold could take between 10 and 20 s to cause unconsciousness and therefore it was safe. Clearly they did not experience the vagal effects of this hold in their experiments. The research of Sauvagneau and Geberth based on videos of fatal autoerotic hangings [23, 24] confirms that unconsciousness is lost after approximately 10 s of neck pressure but that the pressure usually needs to be applied for between 2 and 6 min for death to ensue.

Neck holds are commonly used in many forms of wrestling or martial arts and in these situations they are seldom associated with fatalities possibly because of the ability of the person held to indicate their willingness to submit to a referee and so cause the hold to be released. No such authority is present during a restraint by police and perhaps this is why fatalities are recorded in this situation. In the United Kingdom, the use of neck holds by police during restraint is specifically prohibited and officers are warned during their training of the potentially fatal effects of applying any pressure to the neck. In the USA, however, neck holds are an approved method of restraint.

The pathological examination of deaths associated with compression of the neck requires a detailed and careful dissection of the neck structures [25]. The finding of

WIT.0043.0086.0485

injuries to the muscular, cartilaginous, vascular, or neural components of the neck must, however, be interpreted in the light of the events of the restraint, the actions of the restrainers and the subsequent resuscitation (if any). Pressure on the neck to maintain an airway following cardiac or respiratory arrest may result in bruising which could be confused with pressure prior to, or indeed causing, that arrest. Therapeutic insertion of cannulae during active resuscitation by paramedics or in the hospital very commonly leads to quite marked hemorrhage into the neck which, while it is unlikely to be confused with bruising caused by a neck hold, may mask any bruising that was present.

Pressure on the neck is not, of course, the only mechanism whereby an individual may suffer anoxia or asphyxiation. Any action that occludes, partially or completely, the mouth and/or the nose will result in difficulty in breathing and may result in asphyxiation.

Restraint Asphyxia (See Chap. 7)

The area of restraint that has always caused most concern relates to asphyxiation during the act of restraint. It has been known in forensic circles for many years that individuals may asphyxiate if their ability to breathe is reduced by the position in which they are placed or into which they fall [26]. This type of asphyxiation is commonly associated with alcohol or drug intoxication or, rarely, with neurological diseases which prevent the individual extracting themselves from a position that either occludes, partially or completely, their mouth and nose or which limits the freedom of movement of the chest wall. Death resulting from these events has been described as Postural Asphyxia to indicate that it was the posture of the individual that resulted in the airway obstruction rather than the action of a third party.

In 1988, research by Reay et al. [27] was published which was initially thought to show that, in laboratory conditions, the placing of an individual in the hog-tie position significantly increased the time taken to return to resting blood oxygenation levels following moderate exercise. “Hog-tying” is a form of restraint where the detainee is placed face down and the hands are tied together and then to the feet. Reay concluded that positional restraint (hog-tying) had “measurable physiological effects”. In 1992, Reay published a paper [28] which recorded six cases where, in his opinion, individuals had died as a result of “hog-tying” and being placed prone in police vehicles. This paper raised the possibility that asphyxiation was occurring to individuals when they could not move themselves to safer positions because of the type of restraint used by the police. The concept of “restraint asphyxia”, albeit in a specific set of circumstances, was born.

Since the description of deaths in the prone, hog-tied position, Reay’s original concepts have been extended to account for many deaths of individuals simply under restraint but not in the hog-tied position. The term “restraint asphyxia” has been widened to account for these sudden and unexpected deaths during restraint. Considerable pathological and physiological controversy exists regarding the exact effects of the prone position and hog-tying in the normal effects upon respiration.

WIT.0043.0086.0486

Further experiments by Chan et al. [29] have cast considerable doubt on Reay's thesis although other experiments by Roeggla et al. [30] appear to support the original theory. While the physiological controversy continues, it is clear to all those involved in the examination and investigation of these deaths that there is a small group of individuals who die suddenly and apparently without warning while being restrained.

Physiological research on simulated restraint revealed [31, 32] that restraint did produce reductions in the ventilatory capacity of the experimental subjects but that this did not impair cardiorespiratory function. In two of the eight healthy subjects, breath holding following even moderate exercise was found to induce hypoxia-related dysrhythmias and it was noted that arterial oxygen saturation fell rapidly even with short breath hold times, especially if lung volume was reduced during exhalation.

The problem that currently faces the forensic pathologist is the determination of the cause or causes of these deaths. This is made harder since there are seldom any of the usual asphyxial signs to assist and, even if those signs are present, it is difficult to assign weight or significance to them since similar changes can be caused simply by resuscitation [33].

The major features of asphyxiation are cyanosis, congestion and petechial hemorrhages [13]. These features are seen to a greater or lesser extent in many, but not all, cases of asphyxiation. They often are completely absent in many plastic bag asphyxiations and in hanging, they have variable presence in manual strangulation and they are most commonly seen in ligature strangulation. But their most florid appearance are in deaths associated with postural asphyxia or crush asphyxia cases where death has occurred slowly and where it is associated with some form of pressure or force reducing the ability of the individual to maintain adequate respiratory movement, either from outside the body or from the abdominal contents splinting the diaphragm.

It is of interest then that these features, if present at all in these cases, are, at most, scanty and do not reflect their appearance in other cases of crush asphyxia suggesting that different mechanisms are the cause of death in these two sets of circumstance.

The individuals who die during restraint are not infrequently under the influence of drugs (particularly cocaine) or alcohol, they may be suffering from some underlying natural disease (particularly of the cardiovascular system) or they may have suffered some trauma. These "additional" factors are sometimes seized upon by pathologists and courts to "explain" the death, sometimes even in the face of expert opinion that excludes the additional factor from playing a major part in the death [34].

It would seem that there is a sub-group of the population who are either permanently or at times and for whatever reason susceptible to the effects of restraint whether those effects be mediated entirely or indeed partially through decreased respiratory effort or some other factor.

It should be noted that an individual who is suffering from early, or indeed late, asphyxiation may well struggle more and more in an attempt to breathe and, during a restraint, this increased level of struggling may be perceived by police officers as

an renewed attempt to escape resulting in further restriction of movement and subsequent exacerbation of the asphyxial process. Officers need to be taught that once restrained these further episodes of struggling may signify imminent asphyxiation and not continued attempts to escape—that they may represent a struggle to survive and that the police must be aware of this and respond with that in mind.

Homicide

There have been a number of cases where individuals have been murdered in the cell by another inmate. These deaths are most commonly associated with blunt trauma but strangulation, stabbing and other methods may be employed if suitable weapons are available. It is also evident that individuals have been deliberately assaulted and killed by police officers during arrest and detention.

The HCP should always be aware of the possibility that excessive force may have been applied by the police or that deliberately homicidal injuries may have been inflicted. If injuries are present on any individual in their care these injuries must be carefully documented and, if they are beyond that which the HCP considers reasonable in the circumstances, their concerns should be expressed immediately to a senior officer, a legal representative of the detainee, and through an official complaints procedure. The HCP also has the duty to ensure that no further harm comes to that person.

Self-Inflicted Injuries

Suicidal deaths in custody are a cause for continuing public concern. The methods used are variable but reflect the materials available to the individual at that time.

Hanging

In order to effect a hanging suicide the individual must have two things; an object that can be made into a noose and a point to fix it to. In addition they must be able to place their body so that at least some of their own body weight can be used to apply pressure to their neck via the noose.

The materials and objects that can be made into a noose are legion and vary from the obvious (ties, belts, shoelaces, etc.) to the unusual (underwear, shirts, etc.). In order to attempt to reduce the possibility of hanging suicides, many cells in police stations have been redesigned and attachment points for the noose (pipes, bars, etc.) have been removed or covered. The lack of these obvious points did not, however, previously deter some individuals who placed the bed “on end” and used the upper end as the fixing point. Installation of fixed beds or benching should preclude the use of that method in future. It must be remembered that hanging can still be achieved, although is clearly more difficult, from a low suspension point and any

WIT.0043.0086.0488

protrusion from a wall or fitment in a cell can potentially be used as the upper attachment for the noose.

In addition to removal of the fixing points, attempts have been made to remove the items that have been used as nooses in the past and belts, shoelaces, etc. are sometimes taken from prisoners. Paper clothing has been used although this has not been entirely successful as it entails removing all of the individual's clothing which is clearly impractical in many cases and may raise problems with human rights, and any paper clothing strong enough to withstand any degree of wear would also be strong enough to act as a noose.

The key to preventing hanging suicides lies in the careful evaluation of all individuals who are to be detained (see Chap. 9) and in the design of the cells in which they are held to preclude any possible point for the attachment of a noose.

Given the speed with which hanging can be effected [23, 24], it is most unlikely that anything other than a permanent watch over the suicidal detainee would provide a foolproof method to prevent hanging in a cell. A cycle of 15 min checks will allow more than ample time for an individual to hang themselves and cannot be considered to be adequate protection against this type of suicide.

Ligature Strangulation

As the possibility of suspension is reduced by the changes in the design of the cells, the possibility of other forms of self-asphyxiation are likely to increase. Self-strangulation by ligature is considered to be possible but difficult [13]; since the pressure has to be applied to the neck in these cases by the conscious muscular effort of the hands and arms, it follows that when consciousness is lost and the muscular tone lessens the pressure on the ligature will decrease, the airway obstruction and/or the vascular occlusion will cease and death will generally be averted. If, however, the ligature is knotted or if the material is "non-slip" and looped around itself then it is possible for the individual to apply the pressure to the neck and for that pressure to be maintained even after consciousness is lost and, as a result, death may follow.

As with hanging, the key to preventing these deaths lies in careful evaluation and, if necessary, the removal of items of clothing and observation.

Incised Injuries

All detainees should be carefully searched before incarceration and any sharp objects, or objects that could be sharpened, must be removed. The extent of the search will probably depend on the mental state of the individual and the possibility of an intimate search to exclude weapons concealed in the vagina or rectum should be considered in those individuals considered most at risk. Death from deep incised wounds to the neck or arms can occur very quickly, even if found before death has occurred the effects of profound blood loss may make death inevitable despite attempts at resuscitation.

Drugs

When considering the possibility of suicide using drugs while in police custody the two key factors are, once again, evaluation and searching. Careful searching (possibly including intimate searches in some cases) will prevent the ingestion of drugs by an individual after they have been placed in the cell. The HCP must always be aware of the possibility that excessive quantities of a drug, or drugs, were taken prior to arrest and detention which may exert their effect when the individual is in the cell.

Acute Behavioral Disturbance

Acute behavioural disturbance (ABD) is a term covering a wide range of presenting conditions. In police custody probably the commonest causes are substance misuse (especially stimulant use) and psychiatric disorders. However the differential diagnosis includes a number of conditions:

- psychiatric disorders
- substance misuse (stimulants—cocaine, amphetamine, methamphetamine; synthetic cannabinoids)
- serotonin syndrome
- anticholinergic syndrome
- sepsis
- head injury
- hypoglycaemia
- seizures
- hypoxia
- thyroid storm
- akathisia

ABD and excited delirium or excited delirium syndrome (ExDS), are terms often used interchangeably with only about one third of cases of ABD presenting as ExDS, the most severe end of the spectrum of disturbance [35]. The definition of ExDS has been defined as 'a state of extreme mental and physiological excitement, characterized by extreme agitation, hyperthermia, hostility, exceptional strength, and endurance without apparent fatigue' [36]. It should be noted that Luther V Bell, an American physician, first described ExDS in 1849 [37]. There has been controversy over this diagnosis which is currently not recognized in the Diagnostic Statistical Manual (DSM-V) and the International Classification of Disease (ICD-9). However the diagnosis is recognized as a distinct entity by emergency physicians and medical examiners/pathologists [38] in the USA.

Where ABD/ExDS is suspected individuals should be taken directly to the local hospital emergency department as this is a time critical medical emergency. However should a detainee be taken into police custody the duty HCP needs to recognize the features of ABD/EXDS (Table 13.3) and advise that immediate hospitalization is

WIT.0043.0086.0490

Table 13.3 Clinical Features of ExDS

Tactile hyperthermia
Does not fatigue
Naked/inappropriately clothed
Rapid breathing
Sweating profusely
"Superhuman" strength
Increased pain threshold/tolerance
Constant/near constant activity
Glass attraction-destruction
Non-responsive to others presence
Violent behaviour

required for urgent treatment for the agitation, hyperthermia and acidosis. Whilst awaiting transfer to hospital preliminary steps can be made with regard to diagnosis and causation but any delay to definitive treatment should be avoided. Preliminary steps may include de-escalation and pre-tranquilization.

Guidelines on the management of suspected ABD in police custody are available for these situations [39].

There appears to be significant morbidity and mortality associated with these conditions but the high mortality rate may be due to definition inconsistency and reporting bias [40]. If a death in police custody is suspected to be a result of ABD/ExDS it is essential that a forensic pathologist is involved to conduct the post-mortem and interpret the relevant toxicological analyses. In a cocaine-related death, for example, the plasma levels of cocaine may only be modestly elevated, the heart will invariably be abnormal (enlarged) with microscopic evidence of myocardial remodeling, secondary to chronic cocaine use [41]. Relatives may wish to have an independent pathologist present as is standard practice in the United Kingdom.

Illustrative Case *A young male had taken amphetamines and then started exhibiting bizarre behavior, agitation, paranoia, hallucinations, aggression, overheating, and extreme strength. He left his house in only his underwear. His parents called the police. He was restrained with leg restraints and handcuffs, a spit hood was applied, and he was taken to a police station. During a period of over an hour he remained restrained by six officers. Eventually a forensic physician suggested that he needed to go to hospital as he had taken drugs. An ambulance was called and the male was taken to a police van where he was restrained by three police officers in a caged area. He stopped breathing, and although transported directly to hospital, he died later that day.*

Role of the HCP Following a Death in Custody

If a death occurs in the police custody venue then a HCP may be called to pronounce life extinct. If that HCP has been involved in the earlier care of the deceased then he/she should advise the police that another HCP should be asked to confirm that life is extinct. This avoids any later suggestion of collusion or cover-up.

WIT.0043.0086.0491

Table 13.4 Verification of life extinct [43]

Absence of carotid pulse over 1 min
Absence of heart sounds over 1 min
Absence of respiratory movements and breath sounds over 1 min
Fixed, dilated pupils
No corneal reflexes
No motor response to painful central stimulus e.g. supra-orbital pressure, trapezius squeeze

The HCP who attends to confirm life extinct (Table 13.4) should make very careful records of the scene and condition of the body [42]. However the police will guide the HCP as to the exact extent of the examination till a suitably qualified forensic pathologist arrives at the scene.

Advice should be sought urgently from the forensic pathologist as to whether the body temperature should be obtained; this could help identify deaths from ABD/ExDS and may assist in the determination of the time of death (often a critical factor when the IOPC come to investigate the deaths and questions are asked about the frequency of visits by custody staff). The HCP should ensure that the Scene of Crime Officer/Crime Scene Investigator takes the ambient temperature.

Whenever a death in custody occurs the actions of any HCPs who have been involved in the care of the detainee may be considered during the investigation. Therefore, HCPs should appraise their Clinical Lead/Line Manager/Medical Director of the incident in order to receive advice and support.

The IOPC, Coroner (or equivalent) and internal investigations branch of the police force involved will all be carrying out investigations. There is also a clinical governance requirement for the clinical forensic medical service to review the assessment and treatment of any detainee who dies in police custody to ensure that any lessons are learnt as soon as possible.

Conclusions

The problem for the police remains that while approaching and restraining an individual they cannot know the background or the medical history nor can they have any idea of the particular (or peculiar) physiological responses of that individual. The statistics may suggest that the techniques that have been designed and taught for restraint, and the care of the individual after restraint, appear to be leading to safer restraint by police (and prison officers) of the most vulnerable sections of the community. Unfortunately restraint-related deaths caused by untrained civilian "security" guards appear to be becoming more common—and almost impossible to trace statistically.

The considerable interest by Government and by the public in all forms of deaths in custody over many years now has resulted in the increased availability of reliable and up-to-date statistics. The increased attention to these deaths has also resulted in the necessity for the much more detailed "ECHR Article 2 compliant" inquests

however the inordinate length of time taken by the legal system, both Coronial and Criminal, to complete their consideration of these deaths frustrates much of the immediate understanding of the mechanisms of each individual death and undoubtedly increases the distress of many families, and also of the police officers involved in such a death.

Key Points

Deaths in police custody are particularly important for the following reasons:

- there is always the suspicion that the death was due to an act of commission or omission by the police;
- they are frequently a cause of public concern and create media interest;
- they will always be investigated by independent police officers and the IOPC (or equivalent);
- they are usually subject to a Coroner's inquest (or equivalent) and occasionally are the subject of a public inquiry.

Self-Assessment Exercises

1. What are the main causes of deaths in police custody?
2. What is the definition of Excited Delirium (ExDS)? What are the clinical features of ExDS?
3. What examination is required to verify life extinct?

Traffic Medicine

14

Ian F. Wall and Margaret M. Stark

Learning Objectives

To describe the medical conditions that significantly affect fitness to drive.

To recall the legal limits for alcohol in blood, breath and urine.

To be able to demonstrate the procedure for taking samples from suspected drink and drug drivers.

To explain the effects of common illicit drugs on driving.

To discuss the limitations of Field Impairment Tests.

Introduction

The United Nations established a road safety collaboration in 2011 with the aim of saving lives: the 'Decade of Action for Road Safety 2011–2020'. However the number of road traffic deaths is still rising and the most recently reported figure was 1.35 million in 2016, but the rate of death relative to the size of the world's population remains constant [1]. There are number of key risk factors that are essential to prevent road traffic deaths; these include reducing speed, drink driving, use of motorcycle helmets, seat belts and child restraints. Currently, 123 countries, representing nearly six billion people, have laws that meet best practice for at least one of the five key behavioral risk factors [1].

The estimated road traffic death rate per 100,000 of the population varies. In 2016 in Australia it was 5.6 per 100,000 compared to United States 12.4 and United Kingdom 3.1 [1]. However in the UK there has been little reduction in road deaths

since 2010 and number of seriously injured casualties have increased [2]. Driving a motor vehicle is a complex task requiring a reasonable level of physical fitness, accurate perception, and appropriate judgment. All these factors can be affected by drugs and alcohol, greatly increasing the risk of accidents. Many medical conditions (and their treatments) may impair fitness to drive and will first be considered.

Medical Aspects of Fitness to Drive

Licensing requirements depend on the type of vehicle driven, with more stringent requirements for commercial purposes and multi-axle vehicles.

The legal basis of fitness to drive in the UK lies in the following legislation:

- The European Third Directive on driving licenses (2006/126/EC) effective in the UK in January 2013
- The Road Traffic Act 1988
- The Motor Vehicles (Driving Licences) Regulations 1999 (as amended).

According to Section 92 of the Road Traffic Act 1988:

- A relevant disability is any condition which is either prescribed in regulations or any other disability where driving is likely to be a source of danger to the public. A driver who is suffering from a relevant disability must not be licensed, but there are some prescribed disabilities where licensing is permitted provided certain conditions are met.
- Prospective disabilities are any medical conditions that, because of their progressive or intermittent nature, may develop into relevant disabilities in time e.g. Parkinson's disease and early dementia. A driver with a prospective disability may be granted a driving license for up to 5 years, after which renewal requires further medical review.

In many jurisdictions, including Canada and the United Kingdom, it is the motorist's responsibility to inform the licensing authority of any relevant medical conditions. Similar requirements generally apply in the United States, except that several states (California, Delaware, Nevada, New Jersey and Utah) actually require physicians to report patients with seizures (and other conditions that may alter levels of consciousness) to the department of motor vehicles [3]. Similarly, in two states in Australia (South Australia and the Northern Territory), reporting of patients with seizures (or indeed if the practitioner believes that the person is physically or mentally unfit to be licensed) is compulsory and there are penalties for doctors not reporting [4]. Drivers themselves have a legal responsibility to inform the licensing authority of any injury or medical condition that affects their driving ability, and physicians should take great pains to explain this obligation. Occasionally, especially when dealing with patients suffering from dementia, ethical responsibilities

WIT.0043.0086.0497

may require doctors to breach confidentiality and notify patients against their will or without their knowledge [5]; this situation will be considered later.

Requirements vary in different countries and in different jurisdictions within the same country. When in doubt about the appropriate course of action, physicians or other healthcare professionals should consult the appropriate guidelines. In the United Kingdom, the Driver and Vehicle Licensing Agency (DVLA) has made available a detailed guide for assessing fitness to drive for medical professionals [6]. In Australia, the Austroads Guidelines for Assessing Fitness to Drive provides information [4] and similarly in New Zealand, the NZ Transport Agency [7]. In the European Union, where EC directives have developed basic standards but allow different countries to impose more stringent requirements, there is still considerable variation from country to country. The situation is even more complicated in the United States, where each state sets its own rules, and where Federal regulations for commercial vehicles apply as well. Often, much of the required regulatory information can be acquired via the internet, or from organizations and foundations representing patients who have the particular disease in question [8].

It should be assumed that all adults drive; drivers with disabilities should be given special consideration and may require modification of their vehicle or have certain personal restrictions applied.

Cardiovascular Diseases

A number of studies have demonstrated that natural deaths at the wheel are fairly uncommon and that the risk for other persons is not significant [9, 10]. Even so, requirements for commercial drivers are generally much more rigid than for individuals, and in the United States, the Federal Highway Administration prohibits drivers with angina or recent infarction from driving. The length of prohibition varies from state to state. Restrictions for noncommercial car driving, after first acute myocardial infarction, are 4 weeks in United Kingdom (though only 1 week if treated by percutaneous coronary intervention) but only 2 weeks in Australia (2 days if treated by percutaneous coronary intervention). In the United States, they are entirely at the discretion of the individual physician. In general, myocardial ischemia itself is not considered an absolute driving disqualification, provided treadmill stress testing demonstrates that moderate reserves are present [11]. Similarly, individuals with controlled hypertension are usually considered fit to drive, although physicians, no matter what country they are in, must give serious thought to just what sort of medication is used to control hypertension; clonidine, methyldopa, reserpine, and prazosin can produce somnolence and/or impair reflex responses.

Patients with dysrhythmias, treated with medication or with the implantation of a defibrillator/pacemaker, present a special set of problems [12]. The tendency in the United States has been to treat such individuals as if they were epileptics, i.e., individuals with the potential to lose consciousness at the wheel. Even then, the distinction is not absolute, as some individuals with implanted devices are at much

WIT.0043.0086.0498

higher risk for syncope than others [13], and the ultimate decision remains that of the attending physician.

Most states set minimum requirements for arrhythmia-free periods. Until fairly recently, that period was 6 months in a majority of jurisdictions but is increasingly being shortened to 3 months in many locations. In the UK, patients with implantable cardioverter defibrillators are permanently barred from holding a group 2 license, but may hold a group 1 license providing the device has been implanted for 6 months and has not administered therapy (shock and/or symptomatic antitachycardia pacing) [6].

Epilepsy

Epilepsy is the commonest cause of collapse at the wheel, accounting for approximately 30% of such incidents. In the United Kingdom, epilepsy is a Relevant Disability for purposes of the Traffic Act 1988 (Prescribed Disabilities being severe mental impairment, sudden attacks of disabling giddiness, and inability to meet eyesight requirements) and car driving is not allowed for at least 1 year after a seizure. Here too, restrictions vary from country to country. All 50 of the United States restrict the licenses of epileptics if their seizures are not well controlled by medication. Most states require a 6-month seizure-free period and a physician's statement confirming that the individual's seizures have, in fact, been controlled and that the individual in question poses no risk to public safety. The letter from the physician is then reviewed by a medical advisory board, which may or may not issue a license. In the United States, even if the patient, at some later date, does have a seizure and cause an accident, the physician's act of writing to the board protects him or her from liability under American law, provided the letter was written in good faith.

Withdrawal of antiepileptic medication is associated with a risk of seizure recurrence. One study showed that 41% of patients who stopped treatment slowly developed a recurrence of seizures within 2 years compared with only 22% of patients who continued treatment [14]. Austroads [4] and the DVLA [6] give detailed guidance on driving after physician approved medication reduction. The legal consequences of discontinuing medication, without a physician's order, can be quite devastating. Patients who stop taking antiseizure medication of their own volition and then cause an accident may face future civil liability and possibly even criminal charges if they cause physical injury [15]. Of course, rules vary from country to country, but, in general, a seizure patient who does not inform the appropriate regulatory agency may face dire consequences (including even the legitimate refusal of the insurance carrier to pay for damages).

Diabetes

Diabetes-related hypoglycemia may lead to confusion or loss of consciousness, or from complications of the disease itself, e.g., retinopathy causing visual problems or peripheral vascular disease causing limb disabilities. In the UK, all diabetics

WIT.0043.0086.0499

must meet the criteria to drive and must notify the DVLA. Group 2 license (bus and lorry) requirements are strict, although insulin treated drivers are allowed to drive subject to regular blood glucose testing even on days when not driving, 2 hourly monitoring when driving and an annual review by an independent specialist in diabetes [6]. Similar strict licensing requirements also apply in Australia [4].

In the United States, the situation varies from state to state and states identify drivers with diabetes in a number of ways. In at least 23 states [16] drivers are asked directly if they have diabetes whereas in other states drivers are asked some variation of a question about whether they have a condition that is likely to cause altered perception or loss of consciousness while driving. In some states, physicians are specifically required to notify authorities of the patient's diabetic conditions. As with seizure patients, failure to notify may expose the patient to both civil and criminal liability. Studies have shown that the single most significant factor for drivers with diabetes appears to be a recent history of severe hypoglycaemia, regardless of the type of diabetes or the treatment used [17].

Vision and Eye Disorders

The two most important aspects of vision in relation to driving are visual acuity and visual fields. Visual acuity may simply be defined as the best obtainable vision with or without spectacles or contact lenses. Most countries require a binocular visual acuity greater than 6/12 for licensing purposes. In the United Kingdom, the eyesight requirements are in good daylight, ability to read the registration mark fixed to a vehicle registered under current standards at a distance of 20 m with letters and numbers 79 mm high by 50 mm wide on a car registered since 1 September 2001 or at a distance of 20.5 m with letters and numbers 79 mm high by 57 mm wide on a car registered before 1 September 2001. The minimum field of vision for safe driving is generally regarded as at least 120° on the horizontal when measured with a Goldman III4e target or its equivalent [6].

Ethical Considerations

While it is generally a patient's responsibility to inform the licensing authority of any injury or medical condition that affects their driving, occasionally ethical responsibilities may require a doctor to inform the licensing authorities of a particular problem. If a patient has a medical condition that renders them unfit to drive, the doctor should make sure the patient understands that the condition may impair their ability to drive. If the patient is incapable of understanding this advice, e.g., due to dementia, the doctor should inform the licensing authority immediately [18].

If patients continue to drive when they are not fit to do so, the doctor should make every reasonable effort to persuade them to stop. The doctor may decide to discuss concerns with the patient's relatives, friends and carers as long as the patient agrees.

WIT.0043.0086.0500

If this still does not persuade the patient to stop driving and the doctor is of the opinion that the patient's refusal to stop driving leaves others exposed to risk of death or serious harm, the doctor should disclose relevant medical information immediately, in confidence, to the medical adviser of the licensing authority. Before disclosing this information, the doctor should inform the patient of the decision to do so, and once the licensing authority has been informed, the doctor should also write to the patient to confirm that disclosure has been made and make a note on the patient's record [18].

Alcohol and Driving

Globally it is estimated that 5–35% of all road deaths are reported as alcohol related [1]. In the UK a *drink-drive accident* is a reported incident on a public road in which someone is killed or injured, where at least one of the motor vehicle drivers or riders involved met one of the following criteria:

- failed a roadside breath test by registering above 35 μg of alcohol per 100 mL of breath (in England and Wales) or 22 μg (in Scotland)
- refused to give a breath test specimen when requested by the police (other than when incapable of doing so for medical reasons)
- died, within 12 h of the accident, and was subsequently found to have more than 80 mg of alcohol per 100 mL of blood (in England and Wales) or 50 mg (in Scotland) [19].

The provisional central estimate of the number of deaths in accidents with at least one driver over the alcohol limit for 2017 is 290 with the central estimate of the number of drink-drive casualties of all severities in 2017 is 8660, a decrease of 4% on 2016 [19].

Metabolism of Alcohol [20]

Alcohol is absorbed through the stomach and duodenum. Absorption is dependent on many factors, including age, sex [21], weight and adiposity of the individual, duration of drinking, nature of the drink, and presence of food in the stomach. Alcohol dehydrogenase in the gastric mucosa may contribute substantially to alcohol metabolism (gastric first-pass metabolism), but this effect is generally only evident with low doses and after eating. Studies of alcohol dehydrogenase activity in gastric biopsies of women suggest a significant decrease in activity in women compared with men, which could explain why women have higher peak blood alcohol levels and are more susceptible to liver damage after consumption of smaller quantities of alcohol when compared with men [22]. Further details of alcohol metabolism are given in Chap. 8. Once absorbed, alcohol is eliminated at a fairly constant rate, with 90% being metabolized in the liver and the remainder excreted unchanged in

WIT.0043.0086.0501

urine, breath, and sweat. The rate of elimination in moderate drinkers may vary between 10 and 20 mg/100 mL blood/h, with a mean of 15 mg/100 mL blood/h. Individuals dependent on alcohol, undergoing detoxification, have elimination rates of 19 mg/100 mL blood/h or even higher [23]. This increased rate of alcohol burn off is thought to be a consequence of increased activity of hepatic microsomal enzymes (P450IIE).

Effects of Alcohol on Performance

Alcohol affects mood and behavior, causing euphoria (which is particularly significant in risk taking), but it also produces central nervous system depression. Even at low doses, there is clear evidence that alcohol impairs performance, especially as the faculties that are most sensitive to alcohol are those most important to driving, namely complex perceptual mechanisms and states of divided attention. In a review of over 200 papers [24], a variety of behavioral aspects were examined including reaction time, tracking, concentrated attention, divided attention, information processing, visual function, perception, psychomotor performance, and driver performance. Most of the studies showed impairment at 70 mg/100 mL blood, but approximately 20% showed impairment at concentrations between 10 and 40 mg/100 mL blood.

The definitive study on the relationship between risk of accident and blood alcohol concentration (BAC) was performed in the 1960s in Grand Rapids, Michigan by Borkenstein and Dale [25]; data were collected on 5895 drivers involved in accidents and on 7590 drivers not involved. Comparison of the two groups disclosed that an accident was statistically more likely at blood alcohol levels greater than 80 mg/100 mL blood, with accidents occurring more frequently as follows:

Blood alcohol (mg/100 mL)	Accident occurrence
50–100	1.5 times as frequently
100–150	4 times as frequently
Over 150	18 times as frequently

Further analysis of the data by Allsop [26] quantified the risks for different ages and different drinking habits. On average, the risk doubles at 80 mg/100 mL, increasing sharply to a 10-times risk multiplier at 150 mg/100 mL and a 20-times risk multiplier at 200 mg/100 mL blood. For inexperienced drivers and infrequent drinkers, the sharp increase occurs at much lower levels, whereas for the more experienced drinking driver it may not occur until 100 mg/100 mL (Fig. 14.1).

This research contributed to some countries lowering the allowable BAC for legal driving and in Australia, Canada, the United States and more recently in Scotland. Different concentrations and rules are also applied for younger and/or inexperienced drivers in some countries. As an example, most states in Australia require a zero alcohol level for probationary drivers during their first 3 years of licensing. Further evidence of the relationship between crash risk and blood alcohol levels has been shown by Compton et al. [27] who studied drivers in California and

WIT.0043.0086.0502

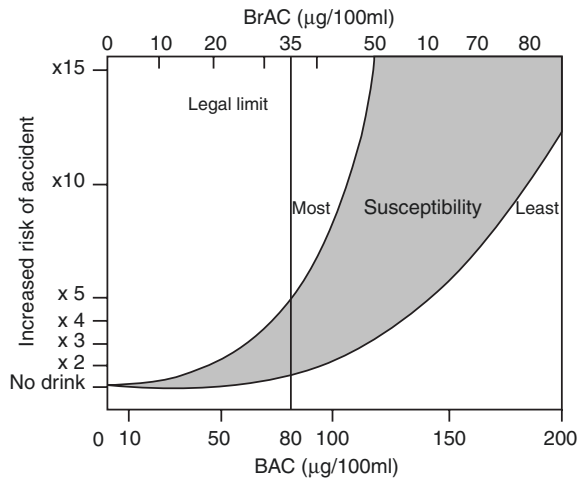

Fig. 14.1 Risk of road traffic accidents related to level of alcohol in the blood and breath. *BAC* blood alcohol concentration, *BrAC* breath alcohol concentration. Permission by Greenwich Medical Media

Florida. This research, surveying a total of 14,985 drivers, produced results that were in agreement with previous studies in showing increasing relative risk as blood alcohol levels increase, with an accelerated rise at levels in excess of 100 mg/100 mL blood. However, after adjustments for missing data (hit-and-run drivers, refusals, etc.), the result was an even more dramatic rise in risk, with the relative risk of crash involvement being significantly elevated at blood alcohol levels of 40 mg/100 mL. More recent research now has concluded that there is strong evidence that someone's ability to drive is affected if they have any alcohol in their blood with drivers with a BAC of between 20 and 50 mg/100 mL having at least three times greater risk of dying in a vehicle crash [28].

Road Traffic Legislation

In the United Kingdom, this research led to the introduction of the Road Safety Act 1967, which set a legal driving limit of 80 mg/100 mL of blood (or 35 µg/100 mL of breath or 107 mg/100 mL of urine). This law also allows mandatory roadside screening tests and requires the provision of blood or urine tests at police stations. The Transport Act 1981 provided that quantitative breath tests, performed with approved devices, could be used as the sole evidence of drunk driving. Although the level for drivers in England and Wales is currently set at 80 mg/100 mL of blood, in practice drivers are not usually prosecuted at blood levels below 87 mg/100 mL of blood because, during the analysis, a series of results by gas chromatography (which must fall within three standard deviations (or 6%) of each other) is averaged, and then 6% (or 6 mg below 100 g/100 mL) is deducted from the result, which is then reported as not less than × mg/100 mL of blood. The North report [29] (see later) recommended that in the United Kingdom, laboratories should apply a 3% allowance to the analysis of blood and urine specimens.

WIT.0043.0086.0503

The legal limits in Scotland were reduced on 5 December 2014 to 50 mg/100 mL of blood (or 22 μg/100 mL breath or 67 mg/100 mL of urine). Recent research [30] has shown that this reduction was not associated with a reduction in road traffic accidents. One plausible explanation cited was that the legislative change was not suitably enforced—for example with random breath testing measures. However a study in the US evaluated the effects of lowering the BAC from 0.10 g/dL to 0.08 g/dL across all 50 states and the District of Columbia and provided strong evidence of the relationship between lowering the BAC limit for driving and the general deterrent effect on impaired driving fatal crash rates [31].

Lower legal limits in Northern Ireland were passed in April 2016 at 50 mg/100 mL of blood and 20 mg/100 mL for learner, novice or professional drivers to bring the levels in line with those in Ireland but have so far not been enacted.

In Australia, the legal limit is set at 50 mg/100 mL for fully licensed drivers for all states but lower levels are in place for other categories of drivers and vary by state e.g. a zero limit for drivers on a learner permit or probationary license, bus and taxi drivers and drivers of trucks over 15 tons.

In the United States, many states have enacted "zero tolerance" laws, and the detection of any alcohol in an individual younger than age 21 is grounds for license revocation.

Equivalent Limits in Other Body Fluids

Statutes have been used to establish BAC equivalents in other tissues and breath. Not infrequently, alcohol concentrations will be measured in accident victims taken for treatment at trauma centers. However, there are two very important differences between alcohol measurements made in hospitals and those made in forensic laboratories; first, in hospitals, standard international units (SI) are the norm, the mole is the unit of mass, the liter is the unit of volume, and alcohol concentrations are reported in mmol/L. In forensic laboratories, results are expressed as gram/deciliter or liter, or even milligrams per milliliter, and measurements are made in whole blood, not serum or plasma. Because 1 mL of whole blood weighs, on average, 1.055 g, a BAC of 100 mg/dL is actually the same as 95 mg/100 g or 21.7 mmol/L [23].

There is another, even more important, difference between serum/plasma and whole blood. The former contains 91.8% water, while the latter contains only 80.1% water. Because alcohol has a very large volume of distribution, this difference in water content means that alcohol concentrations measured in serum/plasma will be higher than concentrations measured in whole blood by approximately 14%. In practice, if plasma alcohol concentrations are to be introduced as evidence, they should be related back to whole blood concentrations using an even higher ratio (1.22:1), which corresponds to the mean value, ±2 standard deviations. As mentioned earlier, if whole blood is tested, drivers are not usually prosecuted at blood levels below 87 mg/100 mL of blood [23].

WIT.0043.0086.0504

Table 14.1 Prescribed blood alcohol levels in various jurisdictions

Australia	50	France	50	Poland	20
Austria	50	Germany	50	Romania	0
Belgium	50	Greece	50	Russia	0
Bulgaria	50	Hungary	0	Slovakia	0
Canada	80	Italy	50	Sweden	20
Czech Republic	0	Lithuania	40	Spain	50
Denmark	50	Luxembourg	50	Turkey	0
Ireland	50	Netherlands	50	US	80
Finland	50	Norway	20		

Breath testing is equally problematic. The instruments used are calibrated to estimate the concentrations of alcohol in whole blood, not plasma or serum. To estimate the serum or plasma alcohol concentration from breath measurements, a plasma/breath ratio of 2600:1 must be used (because, as explained above, whole blood contains 14% less alcohol). In Europe, but not necessarily in the United States or Australia, two specimens of breath are taken for analysis, and the specimen with the lower proportion of alcohol should be used as evidence.

Bladder urine, because it contains alcohol (or other drugs) that may have accumulated over a long period, is generally not considered a suitable specimen for forensic testing, especially since the presence of alcohol in the urine only proves that alcohol is present in the body. Alcohol concentrations in bladder urine cannot be used to infer the blood levels reliably. Even so, U.K. legislation and most U.S. states still allow drivers the option of providing breath, blood, or urine specimens, but as of 1999, the State of California has dropped the option of providing urine samples, and other states are considering similar actions. Under the new California provisions, police can still request a urine test if a suspect's breath test is negative [32].

Other options are available in the case of alcohol-related fatalities. Comparison of alcohol concentrations in vitreous and blood can provide a good indication of whether concentrations were rising or falling at the time of death (alcohol is distributed mainly in water and the water content of vitreous is lower than that of blood). Urine obtained from the kidney pelvis can also be used, since its alcohol content can be precisely related to blood concentration [33].

Legal Limits in Other Jurisdictions

Table 14.1 shows alcohol limits for various countries but many countries have graduated penalties depending on the BAC.

Countermeasures

A number of measures are in place to discourage drivers from drinking, and they have had a considerable degree of success.

Lowering the Legal Limit

When the legal limit was reduced in Sweden from 50 to 20 mg, there was a fall in casualties [34]. It has been estimated that a similar reduction in the United Kingdom would save 50 lives, prevent 250 serious injuries, and eliminate another 1200 slight injuries each year. In 1998, a cost/benefit analysis suggested that this would save £75 million a year [35]. However, the UK Government decided not to implement this reduction. In 2010 the UK Government commissioned a report [29] by Sir Peter North QC to review current drink/drugs driving legislation. He again recommended the lowering of the legal limit to 50 mg but again the UK government decided not to implement this change. Other recommendations were made in his report for drink and drug driving and many of these will be mentioned later in this chapter.

Widening Police Breath Testing Powers

At present, in the United Kingdom, a police officer may stop any person driving a motor vehicle on the road, but that does not necessarily mean that the officer can administer a breath test. The number of breath tests continues to fall in the UK with only 325,887 breath tests carried out by police in 2017, the lowest number since the data collection began in 2002 [36].

In the United States, police officers can require a breath test only if there is reasonable cause to suspect that the person detained has alcohol in their body, has committed a moving traffic offense, or has been involved in an accident. However in Canada mandatory alcohol screening became law in 2018 giving police the authority to demand a breath test of any driver even in the absence of suspicion or cause.

In Finland, random breath testing along with a legal limit of 50 mg/100 mL of blood was introduced in 1977; highly visible check points are established, and typically, 8–12 policemen with breath alcohol screening devices are placed along the center of the road, the sites being chosen so that it is impossible for a driver to avoid being tested. All drivers are tested except those of emergency vehicles. The procedure takes only seconds to perform, the system receives general public support [37], and it has resulted in a marked reduction in the number of accidents and injuries.

In NSW, Australia, random breath testing started in 1982 and trauma from fatal crashes involving alcohol has dropped from about 40% of all fatalities to 15% in 2017 with police conducting about five million breath tests each year in NSW [38].

Ignition Interlocks for Repeat Drink-Drive Offenders

These devices prevent the car ignition from being started unless the concentration of breath alcohol blown into the device is below a predetermined level, often well below the legal limit. Thereafter, during the journey, the driver is required to undertake random rolling retests. A failure of these tests activates the vehicle's lights and horn. All states in the United States have some type of ignition interlock law and several states have made them mandatory or highly incentivized for all convicted drunk drivers, even first time offenders. The same applies in Australia with all States and territories having laws relating to interlock programs. From 1 October 2014 in Victoria, Australia, anyone who loses their license or learner permit due to a drink-driving offense is required to install an alcohol interlock in any vehicle they drive as a condition of relicensing [4]. Results in the United States have shown that repeat offenses

WIT.0043.0086.0506

occur rapidly once the restriction is removed [39]. However, in Alberta, where there is closer supervision of the program, supplemented by counseling, more long-term improvements have been experienced. Though they are currently not the subject of any legal penalty in the United Kingdom, interlock devices can be purchased on a private basis. The North report recommended that best practice on interlock devices should be rolled out throughout the transport industry in the United Kingdom [29].

High-Risk Offender Scheme

A special program in England, Wales, and Scotland was introduced in 1983, and the criteria widened in 1990 to cover drivers who were convicted of having a BAC in excess of 200 mg/100 mL blood, or refusing to provide an evidential specimen, or two offenses involving BACs in excess of 80 mg/100 mL blood within a 10-year period. This group accounts for about 30–40% of drunk driving offenders in Britain. To regain their licenses at the end of a period of disqualification, the drivers must undergo a medical examination (including blood tests to discover biochemical evidence of excessive alcohol consumption) to demonstrate with reasonable certainty that they are not alcohol abusers [6]. Similar statutes apply in the United States. In California, drivers found to have a BAC greater than 200 mg/100 mL, in addition to whatever other sanctions are imposed, are required to attend a 6-month educational program [32]. In the United States, penalties for drunk driving may be "enhanced" under special circumstances, such as a second conviction for drunk driving, or speeding at the time of arrest, or the presence of a child in the car, or the causation of property damage or injury.

Procedural Issues

While the procedures involved may seem very simple, numerous technical defenses have been raised in most countries around the world. Not surprisingly, many of these challenges are very similar, no matter the country in which they are offered. Challenges to the U.K. Road Traffic Act are illustrative of the problem.

Definitions

Section 5(1) of the Road Traffic Act 1988 (subsequently referred to as RTA) states that: if a person drives or attempts to drive a motor vehicle on a road or other public place, or is in charge of a motor vehicle on a road or other public place, after consuming so much alcohol that the proportion of it in his or her breath, blood, or urine exceeds the prescribed limit, he or she is guilty of an offense. Unfortunately, the word "drive" is not actually defined, but in fact, three points need to be proved: first, that the person is in the driving seat or has control of the steering; second, that the person charged must have something to do with the propulsion of the vehicle; and finally, that what the individual was doing must fall within the normal meaning of driving.

Attempting to drive has produced an abundance of case law, but it has been held that acts of mere preparation, e.g., checking the engine, finding keys, or opening the

WIT.0043.0086.0507

car door, do not amount to attempting to drive but steps on the way to what would have been driving, if not interrupted, may amount to an attempt, e.g., putting the key in the ignition. However, in a test case in the UK, when police found a man asleep in his van with the doors locked while over the legal limit, judges ruled by a majority decision that the laws that led to his conviction were "disproportionate" and "violated the presumption of innocence" to which he was entitled under Article 6(2) of the European Convention on Human Rights [40].

In Section 185(1) of the RTA, a motor vehicle is defined as a "mechanically propelled vehicle intended or adapted for use on a road"—the words "mechanically propelled" are intended to have a very wide meaning and will cover any transmission of power from the engine to the wheels by mechanical means. Similar regulations are to be found throughout the EU, and if further evidence is needed as to just how vague the definition of "mechanically propelled" may be, one needs only to consider the arrest, in 1997, of a paraplegic Scandinavian who was arrested (and tried) for unsafe driving of his wheelchair.

In Section 192(1) of the RTA, the word "road" is defined as any highway and any other road to which the public has access and includes bridges over which a road passes. Public place is a question of fact for the court to determine. In English law, a car park attached to a public house was held, during opening hours, to be a public place as it was attached to a tavern that offered its services to all members of the public, whereas the same car park would not be regarded as a public place if it were attached to a private club [41].

"In charge" is a question of fact, not law. As a general rule, the person remains in charge until he or she takes the vehicle off the road unless some intervening act occurs, e.g., handing keys to another person prevents him or her from retaining control. There is a statutory defense in that a person shall be deemed not to be in charge if he or she can prove that, at the time, the circumstances were such that there was no likelihood of his or her driving the vehicle while the proportion of alcohol in the blood was over the prescribed limit. The fact that the driver was injured or that the vehicle was damaged may be disregarded by the court if it is put forward as a defense. The court is therefore entitled to consider what the position would have been had the defendant not been prevented from driving by damage or injury. Of course, the state must always prove that the defendant was actually driving the car. That may prove difficult if, as is the case in many accidents, there are no witnesses.

Breath Testing

Section 6(1) of the RTA conferred the power to require a breath test only to officers in uniform. The courts have already ruled against a challenge where the officer was not wearing his helmet [42]. In the United Kingdom, the breath test may be taken either at or near the place where the officer makes a request for one. Normally, that would be at the roadside, but not necessarily at the scene of the offense. If an accident occurs owing to the presence of a motor vehicle on a road or other public place, a police officer may require any person who he or she has reasonable cause to believe was driving or attempting to drive, or in charge of the vehicle at the time of the

WIT.0043.0086.0508

accident, to provide a specimen of breath for a breath test. The test may be taken at or near the place where the requirement was made or, if the police officer thinks fit, at a police station specified by the officer. The North report [29] recommended that type approval and deployment of portable evidential breath testing equipment should be completed no later than the end of 2011. So far this has not materialized. In the United States, roadside breath testing, with non-evidentiary screening devices, is permitted only in "zero tolerance" states, with drivers under age 21 years. Evidential breath machines have been used at the roadside in Australia for many years.

In the United Kingdom, a person failing to provide a specimen of breath without reasonable excuse is guilty of an offense. A reasonable excuse would include someone who is physically or mentally unable to provide a sample, or if the act of providing the sample would, in some way entail risk to health. In most U.S. states, refusal to submit to a breath (or blood or urine) test is admissible as evidence in criminal proceedings, and as a rule, leads to license suspension, even if guilt is not proved in court. In some states, refusal is actually considered a separate crime. This somewhat strange situation comes about because most U.S. states, and most other countries, have per se laws for alcohol: an alcohol level above some preset limit is, by law, proof of intoxication [43, 44].

Section 6 of the RTA allows police prescribed limit of 35 μg of alcohol a driver without a warrant if the breath test is positive, or if the driver fails or refuses to provide a specimen of breath, and the officer has reasonable cause to suspect alcohol in his or her body. Additionally, if an accident occurs owing to the presence of a motor vehicle on a road or public place, and a police officer reasonably suspects that the accident involved injury to another person, then for the purpose of requiring a breath test or arresting a person, the officer may enter (by force if need be) any place where that person is or where the officer reasonably suspects the person to be.

Hospital Procedure

In the United Kingdom, patients at a hospital do not have to produce a breath test or provide a specimen for a laboratory testing unless the practitioner in immediate charge of their case has been notified and does not object on the grounds that the requirement would be prejudicial to the proper care and treatment of the person. In the United States, forensic blood samples can be taken from unconscious patients who are not able to give informed consent. Legislative changes in the UK in the Police Reform Act 2002 give Health Care Professionals (HCPs) similar powers with a few subtle differences in that blood can be taken providing the person has been involved in an accident, the doctor is satisfied that the person is not able to give valid consent (for whatever reason which could include mental health problems), and the person does not object to or resist the specimen being taken [45]. After death, a coroner can order that the blood alcohol level be measured (remembering always that the value measured will be 14% lower than had serum or plasma been measured at a clinical laboratory). In the United States, Medical Examiners and Coroners do not require special permission to measure ethanol (or any drug for that matter) and they do so routinely. Ethanol concentrations in vitreous humor are made and may be introduced in court. However, no fixed relationship between postmortem blood and

WIT.0043.0086.0509

vitreous concentrations is recognized in law. Additionally, when bodily harm has resulted, or when there is evidence of criminal activity (such as leaving the scene of an accident), then it is within the power of the officer to order that blood be drawn, even if the suspect is unwilling or unconscious.

Police Station Procedure

Police may require a suspect to provide either two breath samples in the UK (other jurisdictions, e.g. NSW Australia, may only require one breath sample), for analysis by means of an approved device, or a sample of blood or urine for laboratory testing. This is usually done at a police station, since it is almost unheard of for a hospital in the United Kingdom or the United States to be equipped with an evidentiary breath testing device. Blood or urine samples can only be collected at a police station or hospital. In the United Kingdom, such a request cannot be made at a police station unless the constable making the requirement has reasonable cause to believe that, for medical reasons, a specimen of breath cannot be provided, or at the time the requirement is made, an approved breath analysis device is not available, or not practical to use, or that the suspected offense is one under Section 3A or 4 of the RTA, and the constable making the requirement has been advised by a HCP that the condition of the person might be due to some drug. This situation does not occur in the United States where, if appropriate staff are available, both blood and urine may be obtained at the police station.

In the United Kingdom, if a specimen other than breath is required, police may demand either a urine or blood test. If blood cannot be obtained as, e.g., might well be the case in a chronic intravenous drug user, then a urine sample must be provided within 1 h of the request for its provision being made and after the provision of a previous specimen of urine. In the United States, urine specimens are generally not considered admissible proof of intoxication. A very large number of studies have shown that the ratio between blood alcohol and pooled urine is highly unreliable and unpredictable [46, 47]. Ureteral urine, on the other hand, has an alcohol concentration 1.3 times greater than blood [33]. Collection of ureteral urine is often attempted at autopsy, but, for obvious reasons, is not an option with living patients. However, blood and not urine can only be taken for Section 5A suspected offenses (see below for more detail).

Breath samples can only be analyzed with approved devices—evidential breath-testing machines (EBM) such as those used in the UK e.g. Intoximeter EC/IR, Lion Intoxilyzer 6000 or CAMIC Datamaster. In Australia this includes models approved by the National Measurement Institute from Drager and Lion (https://www.industry.gov.au/data-and-publications/certificates-of-approval/16-eba). Only officers trained to use the machine are allowed to carry out the intoximeter procedure, and if two breath samples are taken, the lower of two readings is taken. The subject must not have smoked for 10 min or have consumed alcohol or used a mouth spray or mouthwash, taken any medication, or consumed any food for 20 min before the breath test.

If the reading is below the prescribed limit of 35 μg of alcohol per 100 mL of breath, no action is taken unless impairment through drugs is suspected. If that is the

WIT.0043.0086.0510

case, a forensic physician or other healthcare professional should be called. If the level is between 36 and 39, no prosecution can occur unless there is impairment. If the level is 40 or more, the person is charged with an offense, the previous "statutory option" of the person having the option to replace a breath sample between 40 and 50 μg with a sample of blood or urine having been removed following a recommendation of the North report [29] in the Deregulation Act 2015. Different rules and regulations, but with much the same intent, apply in other countries.

Blood Samples

A blood sample may be required in the following circumstances:

- if the suspect is in hospital; or
- in the police station if:
  - the EBM is not available or faulty,
  - the readings are unreliable with a breath difference more than 15%
  - there is the presence of interfering substances;
  - there is a medical reason for failing to provide breath;
  - it is under the excess specified drugs Section 5A RTA 1988.

It is wise to have a standardized routine for this procedure, if only to help prevent some of the technical defenses that are frequently raised in court. RTA blood alcohol kits are available with all the necessary equipment, and similar kits are sold in the United States, although their use is not mandatory. Whether or not a kit is used, appropriate chain of custody forms must be completed, and the record must reflect that alcohol-containing swabs were not used to cleanse the skin (actually, studies have shown that alcohol swabs contribute negligibly to the final result, but the issue has been raised in court) [48].

The police officer should identify the HCP (doctor, nurse or paramedic), to the person and the HCP should obtain witnessed informed consent. The HCP must then determine whether there are any medical reasons why a sample of blood cannot be taken. It is for the HCP to decide where the sample of blood is taken from. The sample should be divided equally between the two bottles and shaken to disperse the preservative. The bottles should be labeled and placed in the secure containers and caps applied. The driver is allowed to retain one sample, which is placed in an envelope and sealed. The driver is then given a list of analysts. Finally the HCP must ensure that the person is fit to be detained or released.

Under U.S. law, blood may be taken even if the driver objects, providing the driver has been involved in an accident leading to injury, or a crime has been committed. Most U.S. states have statutes that excuse hemophiliacs and patients taking anticoagulants from blood testing [32]. In the UK it is suggested that the HCP should attempt to take blood no more than three times with the patient's consent, case law [49] having determined that the person might have lost confidence in the HCP. If the HCP fails to obtain a blood sample then the driver has fulfilled the statutory requirement.

WIT.0043.0086.0511

Impairment Under the Road Traffic Act (Section 4)

The medical examination and procedure to be adopted when it is suspected that a person is unfit through drink or drugs will be considered later in this chapter under Section "Drugs and Driving."

Complex Defenses

Numerous technical defenses have been advocated over the years, and HCPs should be aware of the most common. Failure to provide a sample of breath, blood or urine will be considered separately.

Failure to Provide a Sample of Breath

Unless there is a reasonable excuse, failure to provide a specimen of breath, blood, or urine is an offense under Section 7 of the RTA. In the United States, refusal leads to automatic license suspension and, in some states, may actually constitute a separate crime; police are under an obligation to make sure that drivers are made aware of that fact. The motorist must understand the mandatory warning of prosecution if a specimen is not produced. Failure to understand, at least in the United Kingdom, is a reasonable excuse for the non-provision of a sample [50]. The decision as to whether there is a medical reason not to supply a sample of breath is left to the police officer and is summarized in case law. There is no provision or requirement at that stage for a HCP to be summoned or to give an opinion (Table 14.2).

The role of an Appropriate Adult (AA) (support person) to assist vulnerable individuals with making the decision regarding providing a sample under the Road Traffic Act has recently been clarified. If the individual agrees to provide the sample there is no requirement for an AA to be present. However, if the person detained has declined to provide a sample, the court stated in *Miller v DPP* [55] that there was a very real possibility that the presence of an AA would have calmed the detainee and led him to behave differently and make different choices from those he in fact made.

Table 14.2 Medical reasons for failing to provide a breath sample

Injury to mouth, lip or face
Tracheostomy, rib or chest injury
Respiratory problems such as asthma, acute infections or chronic conditions
Neurological problems, such as facial palsy
Phobia of catching AIDS from using intoximeter [51]
Shock if it renders the driver physically or mentally unable to provide the specimen [52]
Severe alcohol intoxication [53]
Short stature [54]

WIT.0043.0086.0512

The AA can assist the detainee in understanding the gravity of his decision not to provide a specimen.

Many cases have been challenged on the basis that the person was unable to blow into the intoximeter due to respiratory problems. Research has now clarified some of these situations. Spirometry has shown that if a person has a forced expiratory volume in 1 s (FEV_1) of less than 2.0 L and a forced vital capacity (FVC) of less than 2.6 L, then that person would generally be unable to use a breath alcohol testing device [56]. A further study of healthy people of small stature (less than 166 cm tall) showed that if their FEV_1, FVC, and peak expiratory flow rate (PEFR) were greater than 2.31, 2.61, and 330 L/min, respectively, then they should be capable of supplying a suitable breath sample [54]. While these papers were particularly useful as most HCPs do not have access to spirometry but do have access to a simple peak flow reading in the custody situation, most of the breath testing machines that were used in the study no longer exist, the respiratory function values cannot be applied to breath testing devices in current use.

A study in Victoria, Australia, showed that persons with an FEV_1 greater than 1.5 L could provide an adequate screening sample on the Lion Alcolmeter SD2 roadside screening device [57] and that, with an FEV_1 greater than 1.0 and FVC greater than 1.75, individuals were able to provide adequate samples on the Drager Alcotest 7110 (as used in Victoria) evidentiary breath testing machine.

A study [58] on the current Lion Intoxilyzer 6000 concluded that some subjects with lung diseases might have difficulty in providing evidential breath samples. The study showed that 9 of the 30 patients with lung disease failed to provide an evidential sample of breath and was performed on patients who had types of lung disease at the severe end of the spectrum. Importantly, what the research also showed was that many patients had sufficient FVCs of more than 1.5 L and should, in theory, have been able to satisfy the machines' requirements of 1.2 L but still could not, in practice, provide a sample possibly because of the long periods needed for exhalation and recovery.

A recent fashionable defense is that the presence of a metal stud through a hole pierced in the tongue invalidates the breath alcohol test because of the prohibition against foreign substances in the mouth and because of the potential for the jewelry to retain alcohol and interfere with the breath test. However, experimental work has shown that the rates of elimination of mouth alcohol were no different in subjects with a tongue stud as opposed to controls and that, for the purposes of breath alcohol testing, oral jewelry should be treated the same as metallic dental work and left in place without affecting the outcome of the breath test [59].

Failure to Provide a Sample of Blood

First, there must be a definite request to provide a sample of blood. In Kuldip Singh Gill v. DPP [60], it was held that a driver could not be convicted of failing to supply a specimen of blood or urine if he or she was not requested to do so. Where the sample of blood is taken from is solely the choice of the HCP (or, in the United States, the emergency room physician). In Solesbury v. Pugh [61], the defendant was found guilty of failing to supply a specimen, as he would only

WIT.0043.0086.0513

allow a sample to be taken from his big toe, which the doctor was not prepared to do.

It is reasonable for the person to request that his or her own doctor takes the sample of blood, providing this does not delay the sample being taken [62]. In the United Kingdom, if the patient's own doctor and HCP are both present, the person can choose whether the doctor or HCP took the sample. Similar rules apply in the United States, where statutes generally spell out that financial responsibility for such services rests with the driver and not the state. In the United Kingdom, and probably in the United States as well, if a sample of blood is provided but the doctor spills the sample, then the law has been complied with on the basis that removal of the syringe from the vein by the doctor completes the provision of the specimen by the defendant [63]. In the United Kingdom, there is no legal definition on how much blood is required but the specimen must be capable of being divided into two equal parts (to enable the defendant to have a sample independently analysed if they so wished) and it is generally accepted that 5 mL should be sufficient for alcohol. If less than this is obtained, the sample should be discarded and another one attempted or the police officer advised that there is a medical reason why a sample of blood should not be provided and the urine option can then be selected. However, if the offence is for Section 5A a urine option cannot be selected. In the United States, minimum quantities are generally not written into statute. As indicated previously, alcohol swabs should not be used. In the early 1980s, one police force purchased and used swabs containing alcohol with the result that numerous convictions were later quashed [64] (Table 14.3).

Probably, the most common defense for failure to provide a sample of blood is that of needle phobia. If this is alleged, a full medical history should be obtained and enquiry made of whether the person has had blood tests before, whether ears or other parts of the body have been pierced, or whether there have been foreign travel immunizations or any other medical or dental procedure undertaken in which an injection may have been administered. Specific enquiry about the phobia should be made. British appellate judges [65] have stated that "no fear short of phobia recognized by medical science to be as strong and as inhibiting as, for instance, claustrophobia can be allowed to excuse failure to provide a specimen for a laboratory test, and in most if not all cases where the fear of providing it is claimed to be invincible the claim will have to be supported by medical evidence." Stark and Brener [66] stress the importance of having a standardized approach for assessing needle phobia using diagnostic guidelines for a definite diagnosis of a specific phobia and wisely conclude that the best way to ensure a successful prosecution is to obtain a sample, any sample for analysis! Rix [67] also gives some very practical advice for HCPs: be able to distinguish

Table 14.3 Medical reasons for failing to provide a blood sample

Poor venous access
Failure of the HCP to actually take the sample
Needle phobia—need to differentiate between 'dislike' and phobia

WIT.0043.0086.0514

between repugnance and phobia, be able to distinguish between unwillingness and inability, document the history and examination with emphasis on the presence or absence of signs of anxiety, and be sure the decision is based on firm medical evidence. Finally, record all this information, specifically note in the police record whether or not a medical condition has been identified, and then communicate this opinion to the police officers verbally.

Another common defense is that of consuming alcohol after the offense—the hip flask defense [68]. It is used almost universally and is based on the fact that while it is unlawful to have an excessive BAC at the time of driving, it is not unlawful to have an elevated blood alcohol at the time of being tested. In the United Kingdom, Section 15(3) of the RTA allows for a driver to prove that he or she had imbibed alcohol after ceasing to drive and that the amount of such consumption was the sole reason for being over the legal limit or unfit to drive, at the time he or she gave a sample for analysis. It will be necessary for a scientist to prove that it was only the post driving consumption that caused the analysis to reveal an alcohol level above the prescribed limit. The quantity of alcohol in the after-drink, the time of intake, and the age, sex, height, and body weight of the driver can all be used to calculate the theoretical expected BAC [69]. Back calculations can only ever be approximate as they are based on average values and while they are reasonable estimates for most people, they may, on occasions, fail to reflect accurately the situation of a particular individual, regardless of whether the calculation is for pre- or post-incident drinking. There are now computer programmes available to calculate these levels.

But the length a person may go to in order to avoid a conviction is illustrated by the case of Mukandiwa [70] who alleged he could not give a blood sample for spiritual reasons. He was registered as a member of the Zimbabwe National Traditional Healers Association, known as Zinatha, and was authorized to practice healing using both traditional and ritual healing. He was a spirit medium, known as a Mhondoro and, as such, had to avoid situations that drove him into a trance. The sight of blood was one such situation. The sight of blood may, he claimed, cause him to go into a trance and become violent, thereby creating serious risk of injury to his health and to others in the police station. This was held to be a reasonable excuse but subsequently overturned in the High Court, on the basis that the defendant could have looked away or closed his eyes!

Illustrative Case *A 42 year old man was arrested on suspicion of driving whilst over the prescribed limit having blown 42 μg/100 mL of breath on the police officer's hand held breath alcohol machine. At the police station, the evidential breath machine was not working and a forensic physician was requested to see him to take a sample of blood. The detainee stated that he could not provide a blood sample because he had a needle phobia. Preliminary examination revealed that his ears were pierced and he had a number of tattoos on his arms. Whilst the piercing and tattoos would suggest that he did not have a needle phobia, a more detailed history* [66, 67] *was taken and it transpired that the detainee had developed a needle phobia following a dental needle breaking during a dental extraction. It was considered*

WIT.0043.0086.0515

that he did have a genuine needle phobia and that this was a reasonable excuse for providing a blood sample and the forensic physician advised the police officer to continue the drink/drive procedure with a urine option.

Failure to Provide a Sample of Urine

If a woman is requested to provide a sample of urine, it is important to have a female officer present as it has been held that because of the embarrassment that it could involve, the refusal to supply a sample of urine could be regarded as a reasonable excuse [71]. Any embarrassment at having to urinate in front of an officer of the same sex is not regarded as a reasonable excuse for not having supplied a specimen. However, in order to pass urine, it is necessary to relax the bladder sphincter muscles; anxiety causes muscle tension and difficulty in micturition. Self-conscious feelings elicited when others are present may possibly interfere with the ability to relax the bladder sphincters. This is known as avoidance paruresis, sometimes called shy bladder, bashful bladder, or bladder shyness and may be implicated in a defense of failure to provide a sample of urine without reasonable excuse (Table 14.4).

In summary Jones and Logan [69] have outlined a number of driving under the influence (DUI) defenses—see Table 14.5. If the subject has consumed alcohol or other drink or used a mouth spray, mouthwash, drug or medication or has eaten, inhaled or taken anything, or has brought anything back from the stomach, practice in the UK is to wait for 20 min before commencing the evidential breath sampling

Table 14.4 Medical reasons for failing to provide a urine sample

Drugs such as opiates which may result in difficulty passing urine [72]
Neurological problems affecting the bladder
Presence of a catheter
Embarrassment at having to provide a sample in front of a member of the opposite sex
Chronic dialysis patient

Table 14.5 DUI defenses

Drinking after the offense—the hip flask defense

Infusion of blood or other liquids during surgical emergency treatment
Dentures and dentures adhesives

WIT.0043.0086.0516

procedure (MGDD/A 2017). If the subject has smoked (including the use of an electronic cigarette) in the last 5 min, wait 5 min before test.

Illustrative Case *A 28-year-old asthmatic woman was seen to drive a car erratically and was arrested on suspicion of driving whilst over the prescribed limit of alcohol. She gave a history of previous opiate misuse for which she had been maintained on 60 mLs of Methadone per day for the past six months. At the police station she was noticeably wheezy and the police officer elected to request a sample of blood. Two attempts at taking a blood sample were unsuccessful because she had poor venous access due to previous intravenous injections of heroin. The police officer was advised to request a sample of urine for alcohol but the detainee was subsequently unable to provide a sample of urine. She was charged with failure to provide a specimen of urine without reasonable excuse. At the subsequent trial, an expert witness opined that as Methadone can have an effect on the bladder sphincter this was a reasonable excuse* [72] *and the defendant was found not guilty.*

Postmortem Alcohol Measurements

This topic has been reviewed in depth by Pounder and Jones [33]. High postmortem alcohol concentrations do not imply that impairment was evident during life. Of 32 alcohol dependent individuals presented at an emergency room for medical treatment, only 23 had apparent behavioral abnormalities, 6 were confused, and 3 were drowsy, even though the mean alcohol concentration was 313 mg/100 mL (range 180–450 mg/100 mL) [73]. Alcohol can be measured in a number of tissues, but the most accurate picture is usually obtained when multiple sites are sampled, e.g., vitreous, gastric contents, blood, and urine (particularly if ureteral urine is available), and the alcohol concentrations compared.

Since the eye is anatomically isolated, putrefaction is delayed, and there is little problem with postmortem redistribution, vitreous measurements can be used to confirm values obtained from whole blood and urine, to distinguish postmortem alcohol production from antemortem ingestion, and to determine whether BACs were rising or falling at the time of death. Vitreous contains more water than blood so that the blood/vitreous alcohol ratio is less than 1. Ratios greater than 1 suggest that death occurred before equilibrium had been reached, i.e., blood alcohol was still rising [74]. Vitreous alcohol concentrations can be related to blood concentrations; however, there is so much intraindividual variation that extrapolation in an individual case is probably unwise and unsound scientifically.

As previously mentioned, serum and plasma contain more water than whole blood, and it follows that the alcohol content of the former will be 10–15% higher than the latter. Since postmortem measurements are made with whole blood, and since the water content of the cadaver begins to decrease almost immediately after death, estimating antemortem values with any precision is difficult, especially if only blood has been sampled. However, if samples from multiple sites are obtained, and vitreous, blood, and urine (urine as it is being formed contains 1.3

WIT.0043.0086.0517

times as much alcohol as whole blood) are all analyzed, it may be possible to make a reasonable estimate of what the alcohol concentration was at the time of death [33].

Drugs and Driving

The Scale of the Problem

Increasing alcohol levels are associated with increased risk of accidents, but fatigue, illicit drug use, and the use of prescription medication can also increase risk. In recent years there has been a great deal of research to estimate the prevalence of the use of drugs in the driving population. In the United Kingdom in 1997, over 860,000 breath tests for alcohol were carried out with a refusal (presumed positive) rate of 12% (103,000) [75]. During that same period, the Forensic Science Service dealt with only 1850 drugs/driving submissions. In a 2-week period in August 1996, the Forensic Science Service received 270 blood specimens for testing for driving with excess alcohol. Further examination revealed that 18% contained one or more drugs and, of those that fell below the legal alcohol limit, a further 18% were positive for drugs. If this 18% figure were applied to those 103,000 cases in 1997, over 18,000 cases would have been identified in which drivers had drugs in their body [76].

In October 1999, the U.K. Department of Environment, Transport and the Regions completed a 3-year study into the incidence of drugs in road accident fatalities [77]. There were a total of 1138 road user fatalities including drivers, riders of two-wheeled vehicles (34 of them cyclists), passengers in vehicles, and pedestrians; over 6% tested positive for medicinal drugs, 18% for illicit drugs (mainly cannabis), and 12% for alcohol.

In this study, urine was tested by immunoassay for the following drugs: alcohol, amphetamines, methylamphetamines (including ecstasy), cannabis, cocaine, opiates, methadone, LSD, benzodiazepines, and tricyclic antidepressants (TCAs). The incidence of medicinal drugs likely to affect driving had not significantly changed from the 1985 to 1987 study. However, illicit drug taking in drivers had increased sixfold in percentage terms, and there was a comparable increase among passengers. In addition, an increasing number had taken more than one illicit drug. In 1997, drugs were detected in approximately 90% of samples submitted to the U.K. Forensic Science Service for analysis (Table 14.6). Research in Scotland [78] showed that 6% of drivers aged between 17 and 39 claimed to have driven at some time while under the influence of drugs and 3% in the last year.

Table 14.6 Type of drug detected in samples submitted to the FSS in 1997

Amphetamine	13%	Methylamphetamine	3%
Cannabis	28%	Cocaine	6%
Opiates	16%	Methadone	7%
Benzodiazepines	24%	Others	3%

WIT.0043.0086.0518

In Europe the Driving Under the Influence of Drugs (DRUID, Alcohol and Medicines) Project performed in 13 countries over the period 2006–2011 showed that alcohol (>0.1 g/L) was detected in 3.5% of drivers, illicit drugs (mainly cannabis) in 1.9% and medicines (mainly benzodiazepines and some opioids) in 1.4% [79]. There have been studies on road traffic fatalities in the UK with an increase in the presence of illicit drugs from 3% [80] to 18% [81]. More information is becoming available worldwide about the prevalence of driving under the influence of drugs [82].

Effects of Different Drugs on driving

Cannabis

Numerous studies have been undertaken to examine the effects of cannabis on driving. One large meta-analysis of over 150 studies showed that cannabis impairs the skills important for driving, including tracking, psychomotor skills, reaction time, and performance, with the effects most marked in the first 2 h after smoking and with attention, tracking, and psychomotor skills being affected the most [83]. The study also showed that impairment is most marked in the absorption phase as opposed to the elimination phase, and that frequent cannabis users become less impaired than infrequent users. These are, for the most part, older studies, done during the 1970s. Impairment is dosage-dependent, and externally observable symptoms, e.g., impairment of psychomotor skills or the impression of absent-mindedness, disappear quickly during the early elimination phase. One study [84] carried out with volunteer marijuana smokers who were actually driving found that the main effect of marijuana was to increase lateral movement of the vehicle moderately within the driving lane on a highway [85, 86]. A UK study [87] offered further support for the view that, under the influence of cannabis, users are acutely aware of their impairment, but attempted to compensate for their impairment by driving more cautiously. Recent US studies [88] showed that the association between cannabis use and crash risk to be inconsistent. One study estimated the increased crash risk from cannabis usage to be 1.83 times that of an unimpaired driver, while another study found no association between risk of being involved in a crash and cannabis use.

The results of another study [89] suggest that alcohol and marijuana-induced impairment differ in some important respects. This study compared the effects of three doses of cannabis and alcohol (placebo, low and high doses), both alone and in combination, on the driving performance of young, novice drivers, and more experienced drivers. Alcohol was administered as ethanol (95%) mixed with orange juice in doses of approximately 0, 0.4, and 0.6 g/kg. Cannabis was administered by inhalation of smoke from pre-rolled cannabis cigarettes that contained 19 mg delta-9-THC. When the simulated driving performance of 25 experienced and 22 inexperienced drivers was tested under the nine different drug conditions, high levels of cannabis generally induced greater impairment than lower levels, while alcohol at the doses used had few effects and did not produce synergistic effects when combined with cannabis. Both cannabis and alcohol were associated with increases in speed and lateral position variability; high-dose cannabis was associated with

WIT.0043.0086.0519

decreased mean speed, increased mean and variability in headways, and longer reaction time, while in contrast alcohol was associated with a slight increase in mean speed. Given the limitations of the study, it is of great interest to further explore the qualitative impairments in driving performance associated with cannabis and alcohol separately and how these impairments may manifest in terms of crash characteristics. These results may force some reworking of commonly accepted dogma. Finally, there is the issue of testing accuracy. Controlled experiments [90] done with chronic cannabis smokers, living in a locked metabolic ward, show without any reasonable doubt that substantial whole blood THC concentrations persist multiple days after drug discontinuation in heavy chronic cannabis users. Whether or not neurocognitive impairment actually occurs with low blood THC concentrations, and how long it takes to return to normal performance, are not known.

In forensic drug driving cases the level of THC, the active metabolite, and THC-OH the initial metabolite, and THC-COOH the final metabolite, should be measured. High level of THC relative to THC-COOH is indicative of recent smoking of the drug whereas the opposite, when THC-COOH is higher, suggest that cannabis was consumed some time ago. Since the impairing effects of cannabis wear off relatively quickly, this information is very important for the interpretation of the toxicology result. The persistence of blood THC levels maybe higher and persist longer in long term heavy cannabis users [91].

Opiates

Single doses of narcotics can have marked effects on performance, such as reaction time, but the effect of a dose of opiates on driving will depend on the history of usage and whether tolerance has developed. The actual blood level will therefore not necessarily be useful in defining impairment. However, most studies of opiates among regular users suggest that they do not present a hazard or exist as a significant factor in driving. One study [92] compared driving ability between patients stabilized on methadone and those beginning or receiving an increased dose of methadone. A key finding appeared to be that patients on a maintenance dose have no psychomotor impairment in relation to driving ability; thus, clients on a methadone program should not be considered impaired in their ability to perform complex tasks such as driving a motor vehicle. In the United Kingdom, persons on a stable methadone program who have not abused other drugs for 1 year, and who have clear urine drug screening tests on a regular basis, are allowed to hold a driving license subject to annual review [6]. However, it should be remembered that users of heroin are also prone to significant use of other psychoactive drugs, such as cocaine, alcohol, and tranquilizers, all dangerous when it comes to driving.

This problem is illustrated by a study [93] from Germany. Thirty-four methadone substitution patients, all of them volunteers, were subjected to a battery of psychological tests and the results compared with those of a control group. The methadone group ($n = 34$) consisted of 25 men and 9 women (age range 18–38 years). Urine samples of approximately two thirds of the methadone patients tested positive for multiple drug use, the most frequent drug ($n = 14$) being cannabis. On psychological

WIT.0043.0086.0520

testing, the methadone substitution patients achieved lower scores on almost all tests. Performance deficits were particularly conspicuous in sustained attention, sensori-motor coordination, and reaction capability. Deficits were minimal in the 12 methadone patients who were, in fact, taking only methadone. The authors conclude that, under certain conditions, long-term methadone maintenance patients under strict medical supervision do not suffer significant driving impairment, providing that no other drugs have been taken.

These findings were further emphasized in a research paper from Norway [94], where patients enrolled in an opioid-assisted rehabilitation program are also permitted to drive a motor vehicle. Researchers investigated drivers who had been apprehended, who had methadone in their blood. Cases of driving involving methadone alone were very rare. In most cases, benzodiazepines were found with amphetamine type drugs, the most common illegal substance, followed by cannabis derivatives. No correlation between methadone concentration as judged by the Norwegian clinical test of impairment (CTI) was seen.

Heroin may be taken in a variety of ways smoking, by injection, snorting and it has a short half-life of a few minutes before being converted to an active metabolite 6-acetylmorphine (6-AM) and morphine. The active metabolite 6-AM also has a short half-life of about 10–20 min and is therefore only detected in blood for 1–2 h though it may remain in urine for 6–10 h. The presence of 6-AM in blood or urine indicate heroin usage but the period of detection is dependent on a number of variabilities including the heroin dosage, the route of administration and frequency of usage. Presence in urine gives no indication of blood level or impairment.

Cocaine and Methamphetamine

Although the argument often goes unchallenged in court, all drugs do not, by definition, produce impairment. Even though some U.S. states define "being under the influence" as synonymous with the presence of any drug, some drugs do improve performance. In fact, low-to-moderate acute doses of cocaine and amphetamine can be expected to increase positive mood, energy, and alertness, especially in nontolerant individuals [95]. It has been known since World War II that use of d-amphetamine can increase the ability to sustain attention over prolonged periods when performing monotonous tasks. For that very reason, radar operators and pilots of both Allied and Japanese armies were issued supplies of amphetamine. Many of the performance tasks related to driving can be improved, at least in the laboratory, by treatment with stimulants [96]. Although the results of one retrospective autopsy study suggest that methamphetamine users seem more likely to be involved in traffic accidents [97], a driving simulator study [98] of young people who had taken Ecstasy (MDMA) showed that basic vehicle control is only moderately affected but risk taking is increased. It seems likely that abrupt discontinuation of either drug in a chronic user could result in driving impairment, but that situation has never been tested [85]. Very large doses can result in toxic psychosis with symptoms indistinguishable from paranoid schizophrenia, a condition that is extremely unlikely to improve driving performance.

Cocaine and methamphetamine are different drugs, even if they do share some common modes of action. There have been only a few experimental studies on the

WIT.0043.0086.0521

acute effects of cocaine on performance and these are mostly restricted by methodological limitations, such as the administration of low doses. For example, controlled studies of human volunteers given modest doses of cocaine (0.58 mg/kg) failed to demonstrate significant impairment [99]. In most of the studies that have been performed in relation to driving impairment, it was not possible to calculate the associated risks because the number of positive cases was too low. However, other studies [100] clearly demonstrate that drivers under the influence of cocaine are significantly more likely to be responsible for a crash than drivers who are not under the influence of this drug (2.3 OR, 95% CI: 1.4–4.0).

Musshoff and Madea [101] measured cocaine and its principle metabolite, benzoylecgonine, in the blood of German drivers arrested for driving impairment. The finding of cocaine and benzoylecgonine indicates that cocaine was taken very shortly before a blood sample was taken. When blood samples were collected into sodium fluoride containing tubes (which prevent cocaine breakdown), the mean cocaine concentration was 836 ng/mL while that of benzoylecgonine was 669 ng. Given the short half-life of cocaine (in the order of 1 h), concentrations measured in hundreds of milligrams prove recent ingestion, as does the simultaneous detection of both cocaine and benzoylecgonine. However, the detection of benzoylecgonine in isolation cannot be construed as proof of cocaine impairment as one would expect benzoylecgonine to remain present in the blood for more than 24 h. If impairment does occur, the duration of impairment has not been measured. Any per se legislation on cocaine-induced impairment would require the presence of actual cocaine, not any of its metabolites. Once again any symptoms and signs of drug use, as well as evidence of actual impaired driving, are important in the overall conclusions as the same blood concentrations can have significantly different effects on an individual depending on whether they are a regular user and tolerance has developed.

Sedative-Hypnotics

Benzodiazepines impair psychomotor performance in nontolerant individuals, generally in a dose-dependent manner. Most of the widely prescribed benzodiazepines increase lateral lane movement and slow response time to a lead car's change in speed. Several of the benzodiazepines (oxazepam 50 mg, flurazepam 30 mg, and lormetazepam 2 mg) predictably impair driving the morning after. Diazepam (15 mg) impaired performance on a clinical test for drunkenness, which comprised 13 tests assessing motor, vestibular, mental, and behavioral functioning [102, 103]. One study [104] showed a clear relationship between dose of benzodiazepines and risk of impairment, which the authors felt probably supported a limit for benzodiazepines and driving as low as within the "therapeutic range."

Acute doses of many benzodiazepines slow response time in simple or choice visual reaction time tests and impair attentional performance and cause deficits that are not due to sedation. In fact, the impairment of sustained attention and vigilance in benzodiazepine users seems to be the direct result of some, as yet uncharacterized, direct action on perceptual sensitivity [85].

Z-drugs such as zopiclone, zolpidem and zalepon have the potential to impair driving secondary to sedative effects. Patients starting such drugs should be warned

WIT.0043.0086.0522

of the possibility of side effects. Research has shown a decline in driving ability with impaired concentration and coordination [105].

Multiple Drug Use

Polydrug use is common and can result in complex interactions, with the drugs having additive, antagonistic, or synergistic effects. Alcohol is commonly consumed in addition to abused drugs. In a study on alcohol and cannabis [106], it has been shown that when they are administered together, the result was one of additive impairment. This finding was confirmed in a UK study [107]. In the laboratory setting, however, simultaneous administration of alcohol and cocaine seems to minimize alcohol-related deficits [96]. The tendency towards polydrug abuse complicates the issue of determining which drug, if any, is responsible for impairment. In the study by Musshoff cited above [101], more than 50% of those arrested had other drugs besides cocaine present.

Antidepressants

There are many side effects associated with the use of the TCAs, e.g., amitriptyline, that are relevant to the ability to drive, such as blurred vision, slow visual accommodation, disorientation, and eye-hand coordination; the most important are the induction of drowsiness, lethargy, and sedation. An analysis of 500 road traffic accidents showed that victims who had taken TCAs had a relative accident risk 2.2 times greater than non-TCA users and that patients using TCAs with a daily dose greater than or equivalent to amitriptyline 125 mg had a sixfold increase in road traffic crash risk [108]. The newer antidepressants drugs of the 5-HT reuptake inhibitor class, e.g., fluoxetine, paroxetine or the selective serotonin and noradrenaline reuptake inhibitors (e.g., venlafaxine), have been shown to not generally affect driving performance and are safe for use by patients who drive [109].

Over-the-Counter Preparations

An increasing number of drugs can now be bought over the counter from pharmacies. Many of these preparations, e.g., cough mixtures and decongestants, contain drugs that can cause sedation, particularly the older antihistamines, e.g., chlorpheniramine and diphenhydramine. The newer non-sedating antihistamines such as terfenadine and astemizole generally do not appear to impair driving. However, one study that measured driving performance across differing doses of terfenadine found that performance was impaired at very high doses (240 mg), stressing the need to establish the behavioral effects of drugs over a range of doses [110]. The second-generation group of antihistamines is less lipophilic than the previous generation and thus cross the blood–brain barrier less readily, accounting for the lower levels of sedation observed with the newer drugs. Thus, while the second-generation antihistamines generally produce less sedation than first-generation compounds, if therapeutic doses are exceeded, the so-called non-sedating antihistamines become sedating and can impair driving.

WIT.0043.0086.0523

Assessment in the Field by Police

In the United Kingdom, if a police officer stops a driver, for whatever reason, and feels the driver is unfit to drive, it is highly likely that a roadside breath test will be carried out. That is not the case in the United States, where field breath testing is only permitted in some states, and then only for drivers under the age of 21 [32]. The laws of the United States also prevent random breath testing. Under the Fourth Amendment, searches and seizures must be reasonable. Stopping a vehicle is a seizure, but it may be construed as reasonable if the police officer has a justifiable suspicion that an offense is being committed. The procedures American officers follow in DUI cases are surprisingly similar to the procedures under the United Kingdom Section 4 RTA. To gain powers to carry out further tests, officers in most U.S. states first have to be satisfied that the driver is impaired. This then gives them the probable cause to carry out subsequent tests similar to the Section 4 procedure to prove impairment. It is quite possible that some of the newer technologies might be applied in the field to drugs other than alcohol. However, concentrations of THC and THC-COOH in oral fluid show a large variation and there is no correlation between oral fluid and urine samples from cannabis abusers. Thus, detailed information about time interval between drug use and sample collection is needed to interpret the oral fluid results properly, and the value of testing saliva has yet to be convincingly demonstrated [111].

If breath testing is negative, impairment due to drugs or medical illness must be considered. It was previously the case that in the United Kingdom, police traffic officers received little or no training in the recognition of signs and symptoms of drug effects. However, a pilot study [112] was carried out in England, Wales, and Scotland in 1999, whereby police officers were trained to perform roadside impairment tests; this study showed that forensic analysis confirmed the presence of a drug in 92% of the drivers who were suspected of taking a drug, who had failed the Field Impairment Tests (FIT), and who had provided a sample. As a consequence, FIT has been introduced across the United Kingdom with some police forces pursuing it more vigorously than others. This contrasts dramatically with the United States, where in 1979, the Drug Recognition Expert (DRE) Program was introduced. Police officers were trained to observe and document known indicators of drug use and impairment.

In 2004, the Railways and Transport Safety Act (2003) was enacted which introduced in the UK, a Code of Practice for Preliminary Impairment Tests (PIT) making it a legal requirement for motorists to undertake a roadside Preliminary Impairment Test [113]. The Act also provided for the Provision of a Preliminary Drug Test by way of sweat or saliva, though it took some time before these achieved type approval.

In the UK a PIT:

> *'may be a test of any type provided it meets the requirements and objectives of the Act and is administered in accordance with a Code of Practice used by the Secretary of State for the purpose.'*

WIT.0043.0086.0524

The PIT currently includes:

- Pupillary examination
- The Modified Romberg Balance Test
- Walk and Turn Test
- One Leg Stand
- Finger-Nose test.

The codes state it is not possible to 'pass' or 'fail' all or any one of these tests; at the conclusion of the test the constable shall be able to form an overall opinion considering together what they know of the subject's driving, their demeanor and anything learned in general conversation or observation, together with the subject's performance during the test and the observation of the pupillary examination, whether the person is impaired to drive a motor vehicle through drink or drugs. The important factor here is observation where possible of actual driving or evidence from witnesses of the manner of driving.

In the United States instead of breath testing, a series of Standardized Field Sobriety Tests (SFSTs), including test of psychomotor and divided attention skills, is conducted. The following tests are administered when alcohol-induced impairment is suspected: Walk and Turn Test, One Leg Stand, and the Horizontal Gaze Nystagmus Test. If drug use is suspected, a Romberg Balance Test is also administered. Unlike chemical tests, where refusal to submit to testing may result in immediate license suspension, drivers in the United States are not legally required to take any SFSTs; if the driver submits, however, the results can be introduced as additional evidence of impairment.

Various kinds of tests are used. They are designed to assess the individual's balance and coordination as well as the ability to follow simple instructions, i.e., to divide attention between multiple tasks. They are as follows:

- Horizontal Gaze Nystagmus: nystagmus may be caused by any number of conditions, but its presence could indicate drugs or alcohol.
- Walk and Turn: nine steps heel to toe are taken in one direction, and then the individual turns and repeats the process in the other direction. Eight impairment indicators are measured; if two of the eight are present, impairment would be indicated.
- One Leg Stand: the subject has to stand on alternate feet for 30 s while counting aloud. Failing two of the four recognized indicators indicates impairment.
- Romberg Balance Test: the subject stands with eyes closed and estimates a period of 30 s during which body sway is estimated. Some drugs alter the body's internal clock and make the test subject act faster or slower than they normally would. The test allows for a tolerance of ±10 s.

If impairment is identified, and alcohol is suspected, the driver undergoes breath testing and a similar procedure to the United Kingdom Section 5 RTA procedure is

WIT.0043.0086.0525

carried out. However, if drugs are suspected, the police officer calls for a Drug Recognition Expert (DRE) to carry out a more detailed examination.

The DRE uses a 12-step procedure:

1. Breath alcohol test: this is carried out by the arresting officer; if the reading is not consistent with the degree of impairment, the DRE is called in.
2. Interview with the arresting officer: the purpose is to ascertain baseline information including the circumstances of the arrest, whether an accident occurred, whether drugs were found, and if so, what they looked like.
3. Preliminary examination: the purpose of the preliminary examination is to determine whether there is sufficient reason to suspect a drug offense and, if possible, exclude any underlying medical problems. General observations and details of any current medical problems are ascertained, and the first pulse measurement is taken. If no signs of drug influence are found, the procedure is terminated; if any medical problems are found, a medical assessment is obtained, and if drugs are still suspected, a full assessment is carried out. If at any time during the assessment a serious medical condition is suspected, a medical opinion will be obtained.
4. Eye examination: the driver is assessed for horizontal gaze nystagmus, vertical gaze nystagmus, and convergence.
5. Divided attention tests: once at a police station, the Romberg Balance Test, Walk and Turn Test, One Leg Stand Test, and Finger to Nose Test are carried out. These are all examples of divided attention tests designed to assess balance and movement tests in addition to the subject's ability to remember instructions.
6. Vital signs examination: blood pressure, temperature, and a second recording of the pulse are performed.
7. Darkroom examination: pupil size is measured in room light and then in near total darkness, using both indirect artificial light and direct light. The mouth and nose are also examined for evidence of drug use.
8. Muscle tone: limb tone is assessed as some drugs and some drug-related syndromes (particularly the potentially deadly Serotonin Syndrome) cause rigidity, whereas others, e.g., alcohol, cause flaccidity.
9. Injection sites examination: the purpose is to seek evidence of intravenous or injection drug abuse. A third pulse reading is also taken.
10. Interrogation: a structured interview about the use of drugs is carried out.
11. Opinion: based on all the previous assessments, the DRE forms an opinion as to drug impairment and also the type of drug causing the problem, the legal standard being a reasonable degree of certainty.
12. Toxicology testing: at the same time, samples are obtained for toxicologic examination; of either a blood or urine is collected for analysis of common drugs.

Initial studies suggesting very high sensitivity and specificity for DRE examination [114] have not been confirmed in controlled laboratory studies. The results of

WIT.0043.0086.0526

the few studies that have been performed suggest that the accuracy of DRE assessment in general may not be sufficiently good to provide evidence in court fairly [85, 86]. Several field studies have indicated that a DRE's opinions were confirmed by toxicologic analysis in 74–92% of cases when DREs concluded that suspects were impaired. However, published controlled trials, in which blood levels were measured before and during DRE examination, have shown that except in the case of alcohol, DRE assessment agreed with toxicology findings only 32–44% of the time. Evidence has also been obtained [115] to indicate that older people are unable to perform the SFSTs as well as younger people.

Roadside Screening Tests

There are other options for roadside screening tests. Both sweat and saliva have been used [116]. Devices are already available, and some have been approved by the U.S. Department of Transportation for the testing of commercial drivers. Even non-volatile molecules appear in the breath, and the feasibility of even detecting amphetamine by breath testing has been demonstrated [117]. It is very likely that the scope of roadside breath testing will expand in the future. The mere detection of a drug does not prove impairment unless, of course, the jurisdiction has *per se* laws whereby the detection of drugs at some predetermined level is ruled, by law, to be proof of impairment. Roadside drug screening tests are acceptable to the public—a UK study [118] found that 98% of drivers were in favor of the principle of roadside drug screening and found the test methods of saliva or forehead perspiration generally acceptable. In the UK the North Report [29] recommended the earliest practicable type approval and supply to police stations of preliminary drug screening devices and currently two are in use in the UK; the Draeger 5000 and the Securetec Drug Wipe 3S S303G which both test for cannabis and cocaine.

Medical Examination Under Section 4, RTA

In the United Kingdom Section 7(3)(c) of the RTA states that:

> *'the suspected offence is one under Section 3A or 4 of this Act and the constable has been advised by a medical practitioner that the condition of the person required to provide the specimen* ***"might"*** *(author's emphasis) be due to some drug.'*

It is for the court to decide whether the driver is unfit to drive on the evidence before it.

Whether the examination is carried out by a HCP in London, or an emergency room physician in San Francisco, the aim of the examination is to exclude any medical condition other than alcohol or drugs as the cause of the driver's behavior. The differential diagnosis is very wide and includes head injury, neurological problems (e.g., epilepsy, stroke, cerebral tumor, multiple sclerosis), metabolic problems (e.g., hypoglycemia), hepatic or renal failure, and mental illness. The procedure should

WIT.0043.0086.0527

include introductory details, full medical history, and clinical examination. The Faculty of Forensic and Legal Medicine has developed a pro forma for this purpose (see http://www.fflm.ac.uk for the most recent version). Similar forms are not available in the United States, but there is nothing to prevent any emergency department in the United States from drafting and providing a similar document. Even if no special form is provided, most of the relevant material will have been (or at least should be) recorded in the emergency department record.

Introductory Details

These should include the name, address, and date of birth of the driver and the name and number of the police officer as well as the place and date the examination took place. In addition, various times including time a health care professional was contacted, time of arrival at police station/hospital, and time the examination commenced and ended are recorded. The HCP should note the result of any roadside breath test and/or EBM reading; roadside drug screening test; information from the arresting officer—in particular the manner of driving, why the detainee was stopped by police, etc.; the results of the Preliminary Impairment Test (PIT); and the Police Risk assessment in custody. Informed consent should be obtained.

The North Report [29] recommended that appropriately trained HCPs could undertake assessments under Section 4 RTA and this was enacted in the Deregulation Act 2015. The FFLM [119] developed a series of competencies for clinicians undertaking this type of assessment.

Full Medical History

Details of any current medical problems and details of recent events, particularly whether there was a road traffic collision that led to the arrest, should be recorded. Past medical history (with specific reference to diabetes, epilepsy, asthma, visual and hearing problems), past psychiatric history, and alcohol and drug consumption (prescribed, over the counter, and illicit) should be noted.

Interpretation of the findings on clinical examination are only possible if a detailed medical history is taken: physical, mental, drug (prescribed and illicit), as poly drug usage is the norm and dependence and tolerance will need to be considered.

Illustrative Case *A 34-year-old woman crashed her car into a tree. She was assessed by paramedics at the scene and other than a bruised lip, she had no other injuries. A roadside breath test revealed a breath alcohol level of 121 μg/100 mL of breath and she was then arrested on suspicion of driving whilst over the prescribed limit. At the police station she was tearful and distressed and was unable to provide a sample of breath for evidential purposes. In view of the lip injury the police officer decided that this was a reasonable excuse for failing to provide an evidential sample of breath. The HCP was asked to see her to take a blood sample but first decided to*

WIT.0043.0086.0528

assess her fitness for continued detention. This revealed that she was significantly depressed and had been drinking and tried to kill herself by crashing the car into a tree. She stated that on release she would make a further attempt at killing herself. A blood sample was taken but it was deemed that she was not fit for subsequent detention and her admission was arranged to a psychiatric hospital for treatment of her severe depression.

Clinical Examination

This should include general observations on demeanor and behavior, gait, a note of any injuries, speech abnormalities, the condition of the mouth, and any smell on the breath. The cardiovascular system should be examined and, as a minimum, the pulse, blood pressure, and temperature all should be recorded. Evidence of drug use should be sought, e.g., needle marks. Examination of the eyes should include noting the state of the sclera, the state of the pupils including size, reaction to light, convergence, and the presence of both horizontal or vertical nystagmus. The use of drug combinations may result in normalisation of physical signs e.g. normal sized pupils with the use of opiates and cocaine. HCPs need to be aware of 'soft signs' such pupillary reaction to light and the fact that pupil size is also dependent on lighting conditions.

The mental state should be assessed and a sample of handwriting maybe requested. Fitness for detention is of paramount importance, and any person who is not fit to be detained because of illness, injury, or drug and/or alcohol intoxication (toxic effects) and withdrawal should be transferred to hospital and not subjected an assessment under Section 4 RTA. If the person refuses to consent to an examination, it is prudent to make observations on his or her manner, possible unsteadiness, etc. and make written note of these.

Previously it was recommended that the HCPs should repeat a series of divided attention tests, as outlined in Codes of Practice [113]. Despite the fact that these tests are widely applied, Field Impairment Tests (FIT) have never been scientifically or statistically calibrated using a control group of subject drivers who had not taken any drugs. It is therefore not possible to ascertain how any individual driver would perform in the absence of possible impairment due to drugs. Neither is there any clear definition of how many components of the five tests used need to be abnormal before a judgement of impairment can be made. Arguably it would be much better to train both police and HCPs with regard to recognizing the common symptoms and signs of illicit drugs, alcohol and misused prescription drugs (Table 14.7).

Correlation between symptoms and signs of drug use and actual presence of drugs has been found to be low with true positives in subjects who had taken the drug very recently and/or in high quantities [120].

A survey of Police Surgeons' opinions within Strathclyde Police demonstrated concerns regarding the introduction of SFSTs with the Walk and Turn Test and the One Leg Stand Test causing the highest levels of concern [121]. A major review of the evidence by O'Keefe [122] concluded that these tests are not reliable and valid

WIT.0043.0086.0529

Table 14.7 Preliminary Impairment Test (UK) in relation to clinical examination

Test	Observations	Clinical relevance
Pupil examination	Size of pupils	Variation in size with age, lighting conditions, alcohol and/or drugs
	Eyes watery	Sign of opiate withdrawal
	Eyes display reddening	Sign of conjunctival infection, cannabis usage, etc.
Modified Romberg Balance Test	Test for balance	Romberg Test is positive if sways when eyes closed. Indicates impaired proprioception or vestibular dysfunction. Balance[a] affected in cerebellar disease[b] and with CNS depressant drugs.
	Internal clock	Perceptual disturbance may be seen with a range of drugs with the internal clock altered (fast or slow) and not related to the type of drug used
One Leg Stand	Balance and counting out loud	No equivalent examination in the clinical field
Finger-nose test	Test of depth perception and balance	Tests co-ordination Past pointing in cerebellar disease[b] Other tests that might be used: Dysdiadochokinesis Heel knee shin Finger tapping
Walk & Turn	Observation of walking, balancing, and processing instruction	Observation of gait Heel-toe walking may be difficult for older patients (due to the frequent coexistence of other medical conditions) even in the absence of neurological disease. Gait depends on tone, strength, balance[a], sensation and coordination. Presence of abnormalities including ataxic gait seen with CNS depressant drugs such as alcohol

[a]Balance has three components: visual, proprioceptive and vestibular
[b]The cerebellum fine tunes motor activity and assists with balance. Dysfunction results in a loss of coordination and problems with gait

tests of drug related impairment to drive and are too difficult for some groups of drug-free individuals to perform.

At the end of the examination, the clinician should decide whether there is a 'condition' present that might be due to some drug. However opinions differ on what constitutes a '*condition*' due to a drug [123]. In the case of very short-acting drugs, the observations of the police officer or other witnesses can be of crucial importance. An individual has been found guilty of driving while unfit through drugs entirely on the basis of the officer's observations and the results and opinion of the toxicologist—the police surgeon was not called to give evidence [124]. Similarly, if the police officer reports that the person was swerving all over the road, proving good evidence of impaired driving, but the HCP later finds only minimal physical signs, this may be sufficient to indicate that a condition may be present due to some short acting drug, e.g., cannabis, and that it is appropriate to proceed to the next part of the procedure. Case law [125] in the UK has held that the medical

WIT.0043.0086.0530

practitioner (and now the HCP) is entitled to take into account all relevant information relating to the person's earlier condition in determining whether there 'is a condition present which might be due to a drug'. In the United States physicians rarely if ever see individuals arrested under suspicion of impaired driving. Under U.S. law, if a suspected felony has occurred, the driver has no right to refuse testing and a physician may be called upon to draw blood for testing.

The HCP should inform the police officer whether there is a condition present that might be due to a drug and if so, the police officer will then continue with the blood/urine option as in Section 5 RTA, previously described. Consent will need to be obtained for a blood specimen. On this occasion, 10 mL of blood should be taken and divided equally into two septum-capped vials as the laboratory requires a greater volume of blood for analysis because of the large number of drugs potentially affecting driving performance and their limited concentration in body fluids; indeed, if the driver declines the offer of a specimen, both samples should be sent.

As a means of further validating FIT as an effective means of detecting drivers who are impaired due to drugs, the University of Glasgow carried out important research [126]. The drivers stopped under suspicion of impairment who were under the legal alcohol limit, but still considered impaired, were offered a FIT test. If they failed this test, they were considered as a suspect drug driver and examined by a forensic physician and a forensic sample obtained and analyzed if appropriate. Those who "passed" a FIT assessment were asked to voluntarily supply a sample of saliva, which was analyzed for drugs. In relation to the use of FIT, the assessment of impairment by a police officer using the test was supported by the clinical examination of the forensic physician in 77% of cases. Biological samples were only analyzed in 65% of this group, but significant drug use was confirmed in 94% of them. It was not possible to obtain biological specimens from drivers where the forensic physician did not corroborate the opinion of the arresting officer (23% of cases). Importantly, the study confirmed that oral fluid samples could be used to identify drugs in drivers, but of concern was the fact that, of those who were stopped and judged to be unimpaired by the police officer, 71% had drug-positive saliva samples.

In Victoria Australia [127], forensic physicians with relevant qualifications and experience act as experts for the court by reviewing all the evidence of impaired driving, the police Preliminary Impairment Test, the forensic physician's assessment, and toxicological results and provide an opinion. Very few expert opinions have been challenged in court. However, there were a number of inconsistencies in the physical examination with the drugs eventually found on toxicological examination; cases where the individual were barely conscious where a formal assessment should not even have been considered; and missed medical and psychiatric conditions.

Medical Examination Under Section 5A, RTA

Despite the introduction of impairment tests in the UK, convictions for drug driving remained low. The North report recommended that the UK Government should actively pursue research to determine the levels of active and impairing metabolites

of the following controlled drugs: opiates, amphetamines, methamphetamine, cocaine, benzodiazepines, cannabinoids, methadone and ecstasy (MDMA).

An expert panel [128] determined the respective levels based on a road safety risk based approach but following a consultation, the UK Government set a 'lowest accidental exposure limit' for the drugs most associated with illegal use and 'road safety risk based limits' for eight controlled drugs. Legislation was introduced creating a new offence making it unlawful to drive with any of the listed drugs in the body in excess of the prescribed level.

'Accidental exposure'—zero tolerance approach	Threshold limit (μg/L)
Benzoylecogonine	50
Cocaine	10
Delta-9-tetrahydrocannabinol	2
Ketamine	20
Lysergic acid diethylamide (LSD)	1
Methylamphetamine	10
Methylinedioxymethamphetamine (MDMA)	10
6-monoacetylmorphine (heroin)	5

In addition, the UK Government also set levels for certain prescription drugs based on a 'road safety risk based' approach.

'Medicinal' limit—road safety risk based approach	Threshold limit (μg/L)
Clonazepam	50
Diazepam	550
Flunitrazepam	300
Lorazepam	100
Methadone	500
Morphine	80
Oxazepam	300
Temazepam	1000
Amphetamine	250

On 2 March 2015, a new law was introduced as Section 5A of the RTA 1988 via the Crime and Courts Act 2013 making it a new offense to drive with certain controlled drugs, including some prescription drugs, above specified limits, there being no need to prove impairment in Court. Although the legislation has been introduced UK wide, it has not yet been enacted in Scotland or Northern Ireland. There is a statutory defense for drivers who have taken medicines containing specified controlled drugs in accordance with medical advice.

Thus, with the use of a drug screening device, there is no longer a need for a HCP's opinion whether the person has a *'condition that might be due to a drug'*. The levels are set in blood only as levels cannot be set in urine reliability and a urine sample cannot be used as an option for Section 5A cases.

Preliminary results [129] of the new legislation showed increasing convictions for drug driving with more prosecutions under the new Section 5A than for pre-existing

WIT.0043.0086.0532

Section 4 impairment drugs and a conviction rate of 98%. There appeared to be no evidence that users of prescribed medicines that fall into those categories of drugs covered by the legislation had been adversely affected by the new regulations.

Further research continues to try and identify if there are any other alternative biological matrices for use as an evidential sample for drug driving. An expert panel [130] recommended that consideration should be given to expand the list of type-approved screening tests to include, in addition to cannabis and cocaine, the amphetamine type drugs (methamphetamine and MDMA) and ketamine to reflect the growing use of these compounds in the driving population and that hair testing may be an appropriate matrix for re-licensing decisions as it would enable the determination of a history of past exposures to illicit or medicinal controlled substances.

Conclusions

There is an urgent need to reduce drink driving globally as this is a major contributory factor for road traffic collisions with resulting deaths and seriously injured drivers and pedestrians. Since 2014, 22 additional countries have amended their laws on one or more key risk factors to bring them in line with best practice, covering a potential additional one billion people or 14% of the world's population [1]. In the UK there have been repeated calls for Government to reduce the drink drive limit and for a review of policy to reduce unnecessary deaths [131]. There are three approaches to establishing a legal framework for drug driving—zero tolerance, an impairment standard, and a per se approach with many jurisdictions using a combination [132]. The introduction of limits for drug driving has overall simplified the process.

Key Points

- Many medical conditions affect driving. HCPs should be aware of the requirements relating to assessing fitness to drive so they can advise patients accordingly.
- Drink driving limits vary by age, jurisdiction, and type of vehicle.
- It is essential to be aware of the drink and drug driving procedures in your jurisdiction and have a process for taking samples in the police station or hospital.
- There is vast case law on drink and drug driving and it is important to be aware of common examples.

Self-Assessment Exercises

1. How would you advise an insulin dependent diabetic who wanted to apply to be a bus driver?
2. List the factors that affect the absorption, distribution, metabolism, and excretion of alcohol in the body?
3. What are the drink drive limits for alcohol in breath, blood and urine in your jurisdiction?
4. What are the common medical reasons for failing to provide a sample of blood?

Sexual Assault – A Forensic Clinician's Practice Guide 2010

Dr Catherine White

ISBN 978-0-9564737-0-7
Price £150

The author states that the aim of this book is to provide a practical guide for clinicians dealing with sexual assault cases with easily accessible information so that this book can be used during the examination process. This aim is definitely achieved but this book is so much more!

Dr Catherine White is currently the Clinical Director of the St Mary's Sexual Assault Referral Centre (SARC) in Manchester, UK. This was the first SARC in the UK and is still setting the gold standard for other SARCs to aim for.

The book is a high quality loose leafed folder so that updates or local policies and procedures can easily be added. The text is beautifully laid out with tables and appropriate illustrations and to further support the text there are illustrative case studies, key practice points, essential references, and ideas for further reading. There is a section for useful numbers at the back of the book with space for the clinician's personal area numbers. There are also a number of appendices which include examples of pro formas from St Mary's SARC and relevant Faculty of Forensic and Legal Medicine (FFLM) documentation.

There are twenty chapters covering such topics as the basic legislation with regard to sexual offences in the UK – this small section could easily be adapted for other jurisdictions internationally; how to deal with the initial request to attend a complainant of sexual assault; the initial assessment with comprehensive detail on capacity, consent and confidentiality; specific history taking in relation to sexual assault cases; and the examination including an excellent section on anatomy with illustrative line diagrams. Other relevant topics in this field such as emergency contraception, post-exposure prophylaxis, sexually transmitted infection, and the psychological effects of sexual assault are well covered.

The chapters on injuries, forensic samples, alcohol and drugs and in relation to writing statements and attending court will be hugely relevant to all forensic physicians not only those involved in sexual assault. The last chapter is entitled supporting clinicians and suggests support structures such as peer review, appraisals, training, mentorship, supervision, and regular team liaison meetings may result in better recruitment, retention and improved clinical standards. These issues are important to all healthcare professionals working in forensic medicine.

I found the section on child examination very useful even though I am not involved in child sexual abuse examinations. This chapter contains vital information on parental responsibility and safeguarding issues. It is essential that all clinicians involved in the care of children are fully aware of recent developments in this field.

In summary this book is essential reading for all those clinicians involved in sexual assault work but it will also be of interest to other healthcare professionals working in the clinical forensic field. One knows when a true expert has written a book because their knowledge and experience ensure that the content is unambiguous and authoritative.

The author Dr Catherine White has been at the forefront of her field for some years now and it is clear she has a wealth of experience, has learnt from this experience, reflected and refined her practice, and is now using her knowledge, skills and attributes to educate forensic clinicians of the future - a true master in her field.

Guideline

Subject:	**Cleaning/Decontamination of Forensic Examination Suites**
Approval Date:	November 2017, March 2022
Review Date:	March 2026
Reviewed by:	Faculty of Clinical Forensic Medicine Committee
Number:	5/2017

Introduction

This Guideline lays out a set of recommendations for the cleaning and decontamination of forensic examination suites for the purposes of infection control and to minimise DNA contamination of forensic specimens. It is intended for use by forensic physicians involved in setting up or supervising the use of these facilities and any other staff members responsible for maintaining them.

The recommendations in this document should be considered as guidelines and all the details set out in it are not necessarily mandatory. Consultation with other involved parties such as building maintenance, facilities management, hospital infection control and cleaning services is highly recommended. These guidelines should be used to document procedures for each facility with documentation that these procedures have been followed being auditable.

Specialised facilities (suites) used for forensic evidence collection should be cleaned for both infection control purposes and for DNA decontamination. This Guideline provides a framework for both minimum level and best practice in cleaning, decontamination and prevention of contamination of forensic examination suites. The guideline provides protection and reassurance for all participants involved in a forensic examination including the examiner and the person undergoing the examination. It is important to:

- Demonstrate that processes to limit/prevent contamination are part of the forensic procedure; and
- To reassure the public/judicial system that the risk of contamination is being managed/minimised.

1. Principles

- It is not possible to totally prevent DNA contamination, but forensic services need procedures which minimise the risk of contamination and enhance the likelihood that contamination is detected when it occurs.
- It is important to maintain an environment that is welcoming or comfortable for the patient and not frightening or overly 'clinical'.
- Cleaning/decontamination procedures need to be safe and effective.
- Appropriate procedures for the taking of forensic samples which minimise the risk of contamination need to be adhered to.
- Offenders and victims should not be examined in the same suite.

2. Minimum Cleaning Protocol for Forensic Examination Suites

- All surfaces, including the floor should be cleaned regularly (at least after every use) with a non-corrosive detergent. The minimum interval between cleanings should be

determined in consultation with a forensic laboratory and may be dependent on environmental testing.

- Any window ledges or other surfaces that could collect dust should be included in the regular cleaning.
- Cleaning should include the medical examination room, the bathroom and toilet within the facility and the utility room as well as associated interview and waiting rooms.
- Within the medical room, the floor, examination couch, bench tops, writing desk, sink and taps need to be cleaned after every use of the suite.
- Gloves should be worn for all cleaning duties; consideration should be given to the use of gowns and overshoes to minimise the risk of DNA contamination by the cleaner.
- Cleaning of hard surfaces needs to be undertaken with a hospital grade detergent and disposable wipes.
- A register of completed cleaning tasks should be maintained.
- There should be a clear cleaning protocol for the facility cleaners. This should also include an audit schedule and should comply with any existing institutional cleaning policy.

3. Minimum Decontamination Protocol for Forensic Examination Suites

- The suite needs to be decontaminated (cleaned) after an examination to minimise DNA contamination during a subsequent examination.
- Decontamination entails the use of solutions that actively decontaminate DNA – e.g. 0.5% sodium hypochlorite (bleach) which is commonly available under a number of trade names. The solution should be freshly made up before use and must be disposed of afterwards in accordance with any applicable safe handling policies. Users should be aware of the potential for clothing damage due to the corrosive and bleaching action of hypochlorite and should wear gowns or other appropriate protective clothing when using this substance. Standard cleaning detergents do not decontaminate DNA. Most decontaminating solutions need to be left on surfaces for 3-5 minutes. Decontaminant solutions need to be wiped off using a dry white paper towel or dry cloth wipe or may be followed by wiping with 70% ethanol wipes.
- There are some detergent/DNA decontaminant combinations that could be used – e.g. Virachlor™, Actichlor™. These substances enable combined sterilization/DNA decontamination to occur.
- All work surfaces, the examination couch, examination lights, trolleys, bench tops, writing desk, sink and taps need to be decontaminated before each use of the suite.
- In general, non-disposable items such as scissors and forceps should be subjected to hospital grade sterilizing by autoclave. If this is not possible then hypochlorite solution or alcohol based wipes (for items likely to be damaged by bleach) could be used but there no guarantee that this will remove all possible DNA.
- A register of completed decontamination should be maintained. This should record the date and time of the procedure and identify the person doing the work
- Decontamination should be undertaken by cleaning staff who are trained in the procedure (it is not prudent to rely upon medical staff to undertake decontamination).
- Forensic procedures should not be undertaken if the suite has not been decontaminated since the last examination.

4. Operational Measures to Reduce the Risk of Contamination

- The suite should only be used for forensic medical purposes and not for other purposes such as general medical consultations

- The suite should provide appropriate space and equipment to undertake a forensic examination.
- There should be specific evidence kits for the collection of forensic evidence.
- Evidence kits should be stored securely and sealed to prevent interference. Unused contents of open kits should be discarded.
- Where possible other items such as speculums, linen, pillow covers etc used during the procedure should be single use or disposable.
- Plastic wrap should be used to protect difficult to decontaminate items – e.g. colposcope handles. Fresh wrap needs to be applied before each examination.
- Fresh linen needs to be placed on the examination couch immediately prior to each examination.
- A system to ensure that soiled linen is removed and fresh linen applied needs to be in place.
- There must be a system for appropriate disposal of clinical and other waste and for dealing with blood or body fluid spills. This should include notification to the cleaning staff that there has been a spillage so that the affected area can be included in the cleaning procedure. Spillages during a procedure associated with the person being examined should be soaked up with paper towels or similar items but should not necessarily prevent the remainder of the examination from proceeding.
- There must be a system to ensure any used or opened toiletries etc. are removed from the bathroom.
- Powder-free non-latex gloves need to be easily available.
- Changing gloves is an important mechanism to avoid contamination. Separate new clean gloves should be used for:
    - Decontamination/cleaning
    - Setting up equipment and items for the examination
    - Body examination
    - Genital examination
    - Collection of specimens that may leave residue on gloves
    - Collection of clothing
    - Processing of specimens including labelling and sealing samples
    - Selecting more equipment from storage
    - Using examination instruments and cameras
    - It is prudent to postpone photography until after the forensic specimens have been collected in order to avoid the risks of contamination from contact with cameras etc. that are not easily decontaminated.
- All forensic examiners should be trained in evidence collection and should adhere to appropriate swab collection techniques to avoid cross contamination.
- The use of disposable pens and pencils is preferred.
- Disposable scissors or other instruments should be used where possible.
- When using an examination area that is not a dedicated forensic suite, consideration should be given to the use of sterile plastic drapes over trolleys/work benches to protect the placement of forensic swabs etc. Appropriate decontamination is preferable).
- When using an examination area that is not a dedicated forensic suite, consideration should be given to the use of drop sheets to place over other work surfaces.
- If a forensic examiner is required to examine another person immediately following a prior forensic examination, the examiner should wash hands thoroughly and utilise a gown or surgical scrubs and double gloving techniques for the subsequent examination.
- Disposable curtains are preferred. If this is not practicable, then curtains should be washed at least every six months or when soiled. There should be adequate space between curtains and work surfaces to minimise the risk of contamination.

- The forensic examination suite should be kept locked and preferably sealed when not in use.
- Carpet and non-wipe able fabric covered chairs should not be used in the forensic suite.
- Kits or modules should be developed for use by the examiner which are DNA free. Contamination reduction tools such as bench covers, examination couch covers, patient and examiner gowns that have been decontaminated with ethylene oxide should be used whenever possible.

5. Measures to Evaluate the Risk of Contamination

- A log book should be kept detailing use of the forensic suite. This log book should record all persons who have been present in the forensic suites and the integrity of the seals (if any) that are broken when the suite is opened.
- The medical proforma should include a record of people present during an examination.
- Each forensic practitioner should have their DNA recorded on the forensic laboratory exclusion register so that contamination with their profiles can be excluded when specimens are processed.
- There should be clear documentation of any limitations of the examination environment in the medical proforma.

DNA contamination minimisation – finding an effective cleaning method

Kaye N. Ballantyne[a,b]*, Renato Salemi[c], Fabio Guarino[c], James R. Pearson[a], Dale Garlepp[d], Stephen Fowler[c] and Roland A.H. van Oorschot[a]

(*Received 19 October 2014; accepted 10 December 2014*)

Recent environmental monitoring studies have highlighted a need to confirm cleaning procedures are performing to suitable levels for highly sensitive STR kits such as PowerPlex 21. To ensure that DNA contamination minimisation procedures are adequate, we have investigated the efficacy of sodium hypochlorite and a commercial, non-corrosive alternative, Virkon, at a range of concentrations for their DNA decontamination ability. Cleaning solutions were trialled across a range of body fluids and surface types, to cover the variety of potential contamination circumstances encountered within typical forensic laboratories. Given all factors tested, it was concluded that a 1% solution of sodium hypochlorite, sprayed on the surface and left for 5 min before drying and wiping with 70% ethanol, was able to remove DNA, saliva, blood, semen and skin cells from both smooth and pitted surfaces. However, safety testing revealed that the combination of hypochlorite and ethanol produced levels of gaseous chlorine at or above the recommended exposure limits. Subsequently, a cleaning protocol of 1% hypochlorite followed by distilled water was tested for efficacy, and subsequently introduced throughout the laboratory.

Keywords: DNA contamination minimisation; sodium hypochlorite; forensic; decontamination

Downloaded by [Forensic Science Centre] at 13:05 25 March 2015

Introduction

The increasing sensitivity of forensic DNA typing techniques, whilst immensely beneficial for evidentiary analyses, is creating increased challenges to contamination prevention and minimisation during evidence collection and analysis. With PowerPlex 21 now standard across Australia, full 21-locus STR profiles can be obtained from as little as 100 pg[1], compared with 0.6 ng–1.25 ng with older systems such as Profiler Plus[2]. In addition to the increased sensitivity of amplification, continuous DNA interpretation systems such as STRmix[3] are able to deconvolute more complex and highly mixed profiles than previous semi-quantitative systems, allowing the detection of contamination in more samples than ever before.

Contamination has been shown to be one of the most common causes of error in forensic DNA analyses, and can have significant and irreversible consequences for

*Corresponding author. Email: [redacted]

WIT.0043.0093.0003

correct attribution of the source of the DNA[4]. Contamination events have been potentially involved in high profiles cases such as [redacted] (Victoria, Australia), the [redacted] (the Netherlands), [redacted] (Michigan USA), Profile N[10] (New Zealand), and [redacted] (Manchester, UK) to name just a few. In many of these instances, cross-case contamination is thought to have occurred through spatial and temporal proximity of examinations, with indications that DNA was transferred through contact with surfaces and/or tools used to examine both cases. Alternatively, contamination is thought to have occurred from a staff member during examination, or through the presence of background DNA on surfaces. A recent estimation of error rates in forensic DNA analysis from the Netherlands Forensic Institute found that contamination was one of the most common causes of error, with 0.11% of cases showing detectable contaminants across a 5-year period[4].

Previously, we have shown that the transition to the new STR typing methods results in increased detection of background DNA around the forensic laboratory[12]. The percentage of surfaces, equipment and consumables that showed detectable STR profiles increased from 23% with Profiler Plus to 69% with PowerPlex 21, with high risk items such as gloves, forceps and stickers all carrying detectable amounts of DNA. Furthermore, current cleaning protocols in use were found to be insufficient to remove contaminating DNA to levels suitable for PowerPlex 21. A review of cleaning procedures was therefore instigated, aiming to find a cleaning method suitable for use across the laboratory.

There is a surprising lack of empirical research into effective cleaning procedures suitable for forensic environments. Although several papers have investigated decontamination of plasticware and consumables[13–16], and others the effect of cleaning solutions on the ability to recover DNA profiles or perform body fluid identification tests[17,18], there are only two studies we are aware of that systematically compared cleaning solutions for surfaces and equipment[19,20]. The first compared a 5% sodium hypochlorite solution followed by a 70% ethanol wipe with the commercial DNA ZAP (Life Technologies) product, finding that there was not a significant difference between the two solutions except at the lower RFU levels. The second compared 10% sodium hypochlorite with DNA-Exitus Plus (AppliChem), finding that the two methods were comparable. However, both were relatively small studies (seven and eight samples respectively), and either utilised an in-house amplification method, or quantification only, rather than amplification with a commercial STR kit. Further, studies available to date have not investigated a range of surface types, a range of body fluids, or a range of cleaning solution concentrations, all factors that could greatly impact on decontamination levels. Other studies investigating decontamination methods focused on UV-, beta- or gamma-irradiation, ethylene oxide treatment or autoclaving, none of which are suitable for large laboratory areas such as benches or hoods, or sensitive equipment.

Outside of the forensic literature, there is immense variation in the types of solutions recommended and used, with a wide array of commercial products available. For example, Eppendorf recommends cleaning their pipettes with 5% sodium hypochlorite[12], whilst Promega suggests the use of 2–3% sodium hypochlorite for the decontamination of tools[22]. A 10% hypochlorite solution has been recommended for Gilson pipettes[23]. Commercial preparations such as DNA-Exitus Plus, DNA-Away (MBP), Trigene Advance (Trigene), DNA-Off (Pure Biotech) and others most commonly provide agarose gel electrophoresis visualisation results based on nanograms or micrograms of DNA to demonstrate the effectiveness of their product, rather than PCR analysis of minute traces of body fluids and cellular material as encountered in

forensics. Based on the studies listed above, non-forensic decontamination studies[24,25], and manufacturer information, we evaluated the applicability and suitability of cleaning methods and solutions within the forensic laboratory.

Whilst many of the commercial solutions advertise that they are able to completely remove contaminating DNA, the cost of many of these solutions was deemed prohibitive, given the high frequency and extensive cleaning required between items and cases within routine examinations. Some commercial decontamination solutions have been shown to have similar effectiveness to sodium hypochlorite[19,20] (albeit at much higher cost), or to inhibit the DNA profiling process[17]. In others, the active ingredients listed are not known to have a detrimental effect on DNA, and as such are unlikely to provide complete decontamination.

Sodium hypochlorite is known to effectively decontaminate surfaces, and is the most commonly utilised cleaning reagent in laboratories. However, the minimum concentration necessary for effective decontamination is not known. In addition, it is highly corrosive, and can cause skin and eye irritation. Therefore, the use of Virkon (DuPont) was explored as an alternative. This solution, based on the active ingredients potassium peroxymonosulfate and sodium chloride, has previously been used within a forensic laboratory[17], and provides full documentation regarding its active ingredients, ability to destroy nucleic acids, and safety. Key features of Virkon include the non-corrosive nature of the solution, and the built-in colour indicator of activity level, ensuring that out-of-date or ineffective solutions are not used.

The ability for sodium hypochlorite and Virkon at various concentrations to clean different types of body fluids, cells and DNA from a range of surfaces was explored, with the goal of finding an efficient, powerful and cost-effective cleaning method for forensic laboratories.

Methods and materials

Cleaning agent investigation

Optimal concentration

The empirical testing of sodium hypochlorite and Virkon was carried out in a three-stage approach. Initially, varying concentrations of each cleaning solution (sodium hypochlorite – 0.05% (the concentration in use at the time of the study), 1%, 5%, 10% v/v and Virkon 1, 3 and 5% w/v, selected to provide a wide range of concentrations for testing) were tested to determine their ability to destroy 'naked' DNA and DNA within saliva, both as wet and dry stains. All cleaning solutions were used within a week of dilution, and stored at room temperature, with hypochlorite protected from light.

Dried stain: Saliva (10 µl) or extracted DNA (50 ng within 10 µl of DNA IQ (Promega) extraction buffer were pipetted onto sterile glass slides and dried for 24 h. An equal amount of cleaning agent was then added to the stain, and spread by pipetting thoroughly to ensure the entire surface was covered with cleaning agent. Slides were left at room temperature for 5 min, and then immediately swabbed (wet/dry swabbing method[26]) until the surface of the slide was clean.

Wet sample: 10 µl of saliva or DNA solution was placed directly into a sterile microcentrifuge tube, with 10 µl of the cleaning agent, and mixed thoroughly by pipetting.

All samples, including control deposits not treated with any cleaning agent, were then DNA profiled as described below, with all performed in triplicate.

WIT.0043.0093.0005

Surface decontamination

Following selection of the optimal concentration of the cleaning solution (1% hypochlorite and 5% Virkon), each solution was evaluated for its use on both smooth and rough surfaces, with blood, semen and skin. Controlled areas (10 cm^2) of smooth plastic, smooth steel and pitted plastic were used to simulate different environmental surfaces commonly encountered within the laboratory. For each surface, 10 µl of freshly drawn, non-coagulated blood, 10 µl of semen, or touch (hands were rubbed vigorously together before deposition; control samples showed approximately equal deposition between prints) were deposited and allowed to dry for 30 min (skin) to 2 h (blood and semen). Following this, each was cleaned by spraying the deposition thoroughly with the cleaning solution, left for 5 min, and wiped dry. All sodium hypochlorite samples were subsequently sprayed with 70% ethanol and wiped dry (as this is standard procedure with hypochlorite to remove chlorite residue to prevent corrosion). To enable direct comparison, half of the Virkon-cleaned samples were also cleaned with ethanol in the same manner. All surfaces were then swabbed in the standard wet/dry manner. All samples, including control deposits not treated with any cleaning agent, were then DNA profiled as described below, with all performed in triplicate.

Effect of ethanol on cleaning effectiveness

During initial implementation of the revised cleaning method, concerns were raised regarding the formation of hazardous gases (chloroform and/or chlorine). Following testing (described below), revised experiments were performed with 1% hypochlorite used to clean blood and skin cells deposited on smooth and pitted plastic as described above. Within these tests, half of the samples were cleaned with 1% hypochlorite as described above followed by a 70% ethanol clean, and half were cleaned with 1% hypochlorite followed by a distilled water clean. Subsequent testing regarding the effectiveness of a 5 min cleaning time utilised 1% hypochlorite with a distilled water clean, with the hypochlorite either left on the surface for 5 min or wiped dry immediately. The effect of cleaning time was tested on DNA, blood, saliva and skin deposited as described above on smooth plastic and steel, and on a selection of commonly used items from the laboratory (ruler, pen, keyboard, Hemastix bottle and a metal tape measure. All surfaces were then swabbed in the standard wet/dry manner. All samples, including control deposits not treated with any cleaning agent, were then DNA profiled as described below, with all performed in triplicate.

DNA profiling

Following sampling, DNA was extracted with DNA IQ (Promega) on a Biomek Nxp liquid handling platform (Beckman Coulter) to a final volume of 50 µl. Quantitation was performed with the Quantifiler Human DNA Quantification kit (Life Technologies), and STR amplification with the PowerPlex21 System (Promega) as per the manufacturer's recommendations on robotic platforms. All amplifications were analysed on the 3500xL Genetic Analyser (Life Technologies) according to standard laboratory methods, and analysed with GeneMapper ID-X with a baseline threshold of 175RFU, where any profiles without peaks above 175RFU were considered negative. The average number of alleles and peak height was calculated for each category – in some instances, negative profiles caused the average peak height to be below 175RFU. In all such

Downloaded by [Forensic Science Centre] at 13:05 25 March 2015

WIT.0043.0093.0006

cases, two of the three replicates were negative, with the remaining replicate displaying low peak heights and numbers of alleles.

Chloroform and chlorine testing

In response to health and safety concerns regarding the combination of hypochlorite and ethanol, testing was performed to determine if hazardous levels of chloroform and/or chlorine were being released during cleaning. Chloroform testing was performed in several stages. Initially, a stock 12.5% solution of hypochlorite was used. Separately, either 1 mL of hypochlorite, 1 mL of (absolute) ethanol, or a mixture of 1 mL of each was added to a 500 ml Schott bottle, and passive headspace collection with charcoal tubes was performed for 1.25–1.5 h. Analytes were extracted by gravity flow with 1 ml toluene, and analysed with GC-MS.

Subsequently, environment testing was performed within a small enclosed space (Perspex glovebox, 58×55×47 cm), and within the general laboratory (large open space). For the enclosed testing, the interior of the box was sprayed with hypochlorite until visibly wet, left for 5 min, wiped, sprayed with 70% ethanol and wiped again. A charcoal tube was suspended in the box after the 5 min incubation of hypochlorite (prior to wiping and ethanol application), and allowed to passively absorb the headspace for 2 h. Within the laboratory, charcoal tubes were hung above benches (15 cm above surface, approximately face-height for most examiners) during cleaning with 1% hypochlorite and 70% ethanol, as per standard laboratory procedures. Tubes were allowed to absorb for 1 h after cleaning, during which time the benches were not used. All tubes were processed for the presence of chloroform as described above.

The presence of chlorine was detected with a handheld gas monitor (able to read 0.01–50 ppm chlorine) whilst cleaning was conducted within a controlled environment. Chlorine levels were measured during the spraying of 0.25, 0.5, 0.75 and 1% hypochlorite, during the wiping/drying of hypochlorite, and during the spraying and wiping of 70% ethanol. In addition, the level of chlorine released during a secondary water spray and wipe, following a hypochlorite spray and wipe, was investigated, as well as a three-stage clean with hypochlorite, water and ethanol. Chlorine readings were taken at both bench level and standing height.

Results and discussion

Optimal concentration of cleaning agents

Initially, the effectiveness of sodium hypochlorite and Virkon was evaluated at a range of concentrations for their ability to destroy both wet and dry extracted DNA and saliva. The positive controls of dried DNA and saliva produced, as expected, full profiles with peak heights averaging 5000–6000 RFU (Figure 1). All deposits treated with 0.05% hypochlorite produced complete profiles, with average peak heights of ~6500 RFU, and with up to 150 ng of DNA recovered from treated deposits. However, increasing the concentration of hypochlorite to 1% or greater completely eliminated all DNA from both wet and dried stains.

In contrast, Virkon was not able to destroy all DNA, particularly in saliva where 36–39 alleles were observed from samples treated with 1% Virkon, 1–38 alleles with 3% Virkon, and 0–6 alleles with 5% Virkon. It was more effective with extracted DNA, with only one wet DNA sample showing four alleles with 3% Virkon treatment

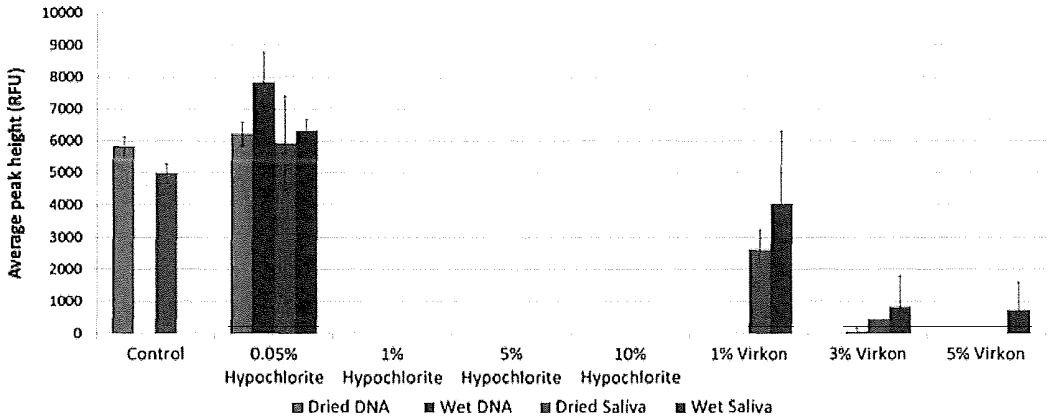

Figure 1. The effect of cleaning agent and concentration on the average peak height of alleles observed in PP21. Each bar represents three replicates; error bars represent 95% standard deviation. Controls for wet DNA and wet saliva were not performed.

(Figure 1). It is theorised that the proteins, electrolytes and cellular components within saliva may be inhibiting the active ingredients within Virkon.

From these data, it was concluded that a 1% sodium hypochlorite solution is sufficient to destroy DNA, whilst a 5% Virkon provided maximum decontamination possible for the solution. It should be noted that a higher concentration of Virkon could not be tested, as the manufacturer recommends that 4% is the maximum concentration that can be made. However, we found that 5% w/v was able to be dissolved completely, and remained stable.

Surface decontamination effectiveness

The two cleaning agents were subsequently tested for their ability to clean three different surfaces contaminated with three different body fluids. In addition, the effect of removal of Virkon residue with ethanol was tested. Substantial differences in cleaning efficacy were observed between the different conditions (Figure 2).

Hypochlorite with an ethanol wipe was able to effectively clean the contaminating body fluids on both smooth plastic and steel across all replicates. However, it was not able to completely decontaminate samples on pitted plastic, with low amounts of DNA recovered (<50 pg total) and small numbers of alleles in both blood and touch samples.

The use of Virkon alone proved to be ineffective on both blood and semen samples on all surfaces, with measureable DNA concentrations and positive amplifications in all categories. However, Virkon was most effective at removing touch deposits, with no positive amplifications for any skin samples treated with 5% Virkon alone, or 5% Virkon with ethanol.

The use of a secondary ethanol wipe subsequent to initial cleaning with 5% Virkon proved to produce contradictory results – in some cases, substantially more DNA was recovered following the use of ethanol. It is possible that as Virkon does not appear to destroy cellular DNA effectively (as seen during initial concentration testing), the ethanol may have acted as a surfactant and lysing agent, making the remaining DNA more accessible to swabbing. This did not occur with touch DNA, possibly as there is less initial DNA present, and because a higher proportion of DNA is not enclosed within

cellular membranes and nuclei[27,28]. However, it should be noted that in all cases except blood on pitted plastic the peak heights were very low (<500 RFU), which indicates that the vast majority of the deposited sample was destroyed/wiped away during cleaning.

The results suggested that 1% hypochlorite, followed by a secondary ethanol wipe, would be the most effective cleaning method across the range of surfaces and body fluids encountered within the laboratory. As a consequence, this method was introduced within the Biology Division at VPFSD, and environmental monitoring was performed to confirm results obtained in controlled trials. Samples from cleaned items (n=24) showed a substantial drop in the amount of background DNA, with a three-fold reduction in the levels observed, compared with that seen from similar items with 0.05% hypochlorite. Although 33% of samples taken did display detectable levels of DNA (ranging from 1 to 5 alleles; peak heights all under 500 RFU), this represents a substantial decrease in contamination levels compared with those seen previously with 0.05% hypochlorite (53% of samples positive; 1–58 alleles; peak heights under 1200 RFU)[12]. In addition, surfaces cleaned with 1% hypochlorite, which did not have detectable profiles or quantitation results did not show low-level peaks below the 175 RFU threshold, whilst those cleaned with 0.05% showed up to 28 additional alleles below the threshold.

However, following the widespread introduction of 1% hypochlorite and ethanol, concerns were raised regarding potentially hazardous gases being produced. In particular, it was postulated that the two solutions were combining to produce chloroform, resulting in headaches and eye irritation amongst staff exposed. It is known that hypochlorite can combine with substances in use in DNA laboratories such as guanidine thiocyanate (a key component in DNA IQ extraction systems) to generate toxic gas, but the combination of hypochlorite and ethanol has not yet been investigated to our knowledge, despite its general use and wide acceptance. To explore this, a range of samples were taken from liquid hypochlorite, combined liquid hypochlorite and ethanol, sprayed and wiped hypochlorite and ethanol in confined spaces, and sprayed and wiped hypochlorite in open areas. Headspace collection of vapours followed by GC-MS analysis demonstrated that chloroform is produced in high concentration when 1%

WIT.0043.0093.0010

hypochlorite and ethanol are mixed as liquids at room temperature within a closed environment. However, even within a small closed environment, when used according to the standard cleaning method where the hypochlorite is dried thoroughly prior to the application of ethanol, no chloroform was detected. If, however, the ethanol is sprayed onto surfaces still wet with hypochlorite, chloroform is produced at approximately 6 ppm, below the WorkSafe Australia exposure standard for chloroform at 10 ppm. Within an open laboratory environment, no chloroform could be detected above or around benches being actively cleaned with hypochlorite and ethanol.

On the other hand, analysis showed that chlorine gas was being produced during the cleaning process, at times above the recommended exposure levels, albeit briefly. Extensive testing showed that no chlorine is released upon the spraying of the hypochlorite solution itself, but that it is the application of ethanol that enables the chlorine to become vaporised (Figure 3). The amount of chlorine released is relatively constant, with detectable levels being produced with both 0.25% and 1% hypochlorite and ethanol. If water is used as the secondary cleaning solution, no detectable chlorine is produced. Chlorine can be detected in low amounts from cleaning waste (paper towel) immediately after use, but at a level below the recommended maximum exposure.

In light of the chlorine testing, the cleaning ability of 1% hypochlorite followed by distilled water was investigated. In addition, the use of a lower concentration of hypochlorite (0.25%) was investigated to further limit the potential hazard. As before, blood and skin was deposited onto smooth and pitted plastic, and cleaned in the appropriate manner. The results in Figure 4 show that whilst there was no significant difference in the decontamination of surfaces between the ethanol- and water-treated samples ($p = 0.484$), ethanol performed slightly better in the decontamination of blood samples. The 0.25% failed to destroy the DNA to a level equivalent to 1% (p=0.024).

Subsequent environmental monitoring around the laboratory of 1% hypochlorite followed by a water wipe (n=15) indicated a slight increase in the level of DNA present on items compared with the use of an ethanol wipe (from 33% of items with detectable DNA to 41%), but peak heights remained low (<400 RFU), and the number of alleles (maximum of 7 observed) indicated that only trace levels of DNA were remaining on

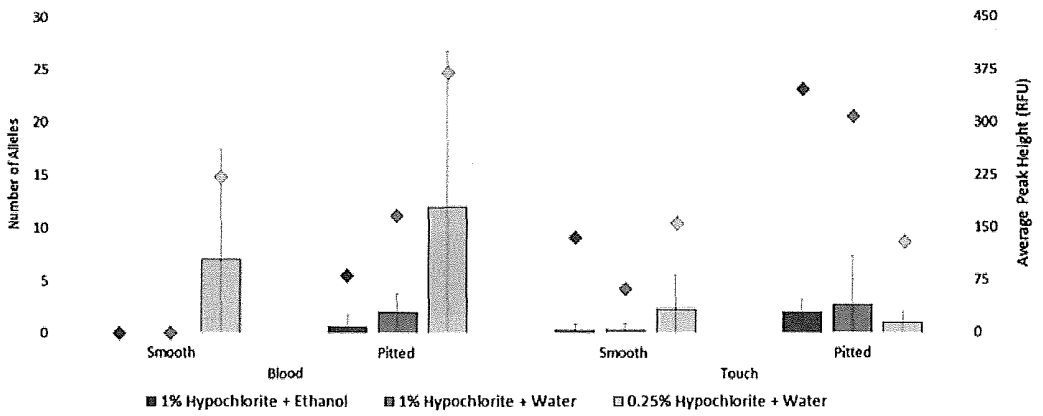

Figure 4. The effect of ethanol and hypochlorite concentration on the number of alleles (bars; left axis) and average peak heights (diamonds; right axis) observed following PP21 amplification. Figure 5. The effect of leaving hypochlorite to soak on the surface for 5 min on the number of alleles (bars; left axis) and average peak heights (diamonds; right axis) observed following PP21 amplification. Each category represents three replicates; error bars represent 95% standard deviation. Average peak heights below 175 RFU represent categories where two of the three samples did not display detectable alleles (peak height of zero).

items, at levels that were unlikely to be detectable if transferred. Previous research has shown that the percentage transfer of dried biological material and touch DNA is very low, generally below 1%[29,30].

To further reduce the potential exposure to hypochlorite, the effect of the cleaning time, where hypochlorite is left on the surface being cleaned for at least 5 min, was also explored. Controlled deposits of DNA, blood, saliva and skin cells on smooth plastic and steel cleaned with and without the 5 min soak time showed that overall there was little effect of time (Figure 5). Although increased quantities of DNA were observed with blood, incomplete decontamination of two of the six samples containing 19 and 20 alleles each caused this increased average. All other samples on these substrates with blood were negative. Likewise, cleaning with a 5 min soak time did not appear as effective as immediate cleaning for saliva on smooth steel in one sample (11 alleles), although the other two replicates were negative. Overall, however, there were no significant differences in levels of contamination observed, when hypochlorite was left for 5 min or cleaned immediately, in quantities recovered, number of alleles or peak heights observed (all p-values > 0.25). Subsequent testing on commonly used items likewise showed little difference between cleaning times, with an average of 3.4 alleles with peak height of 300 RFU with immediate cleaning, and 4.9 alleles and 155 RFU with a 5 min wait. Based on these data, it can be concluded that the 5 min wait time is unnecessary, although care should be taken with visible deposits of blood and with surfaces that may contain small pits and cracks, which may be difficult to clean fully.

Following the testing described above, VPFSD has introduced a 1% hypochlorite plus subsequent water wipe method of cleaning throughout the laboratory, a method that has been shown to effectively decontaminate contaminated surfaces, and is safe for use.

Department of Health

Queensland Government

MEMORANDUM

To: Health Services Chief Executives, Hospital and Health Services

Copies to: Deputy Director-General, Strategy Policy and Planning Division
Deputy Director-General, Clinical Excellence Division
Chief Executive Officer, Health Support Queensland

From: Michael Walsh, Director-General, Queensland Health **Contact No:** [redacted]

Subject: **Health Service Directive: Caring for people Disclosing Sexual Assault**

File Ref: **C-ECTF-19/8477**

Thank you for participating in the consultation process on the Health Service Directive: Caring for People Disclosing Sexual Assault (the Directive) and the Guideline for the Management of Care for Adults (14 years and over) Disclosing Sexual Assault (the Guideline). I have now approved this Directive and Guideline for publication.

The Directive, which is effective from 22 July 2019, requires Hospital and Health Services to take a consistent approach to managing the clinical and psychosocial needs of people who have experienced sexual assault. It includes the person-centred provision of forensic examinations including the Just in Case option which allow victims to access a forensic examination without police involvement. This aligns with our commitment to put patients first.

The Guideline supports the management of Adult (14 years and over) Victims of Sexual Assault recognising that services can be adapted as appropriate to suit local capabilities. This will be particularly relevant during the implementation period. While effective from 22 July 2019, it is appreciated that compliance will be progressive.

The effort required by Hospital and Health Services to implement sexual assault support services is acknowledged. To support this, the Department is funding and coordinating a training program for nurses; recruiting a dedicated Assistant Director of Nursing position to lead nurses involved in sexual assault support services; and will continue to provide telephone support through the Clinical Forensic Medicine Unit, Forensic and Scientific Services, Health Support Queensland. Information and resources to support this service delivery will be made available on QHEPS.

The attached Directive and Guideline will be published on the Queensland Health Policy and Health Service Directives website at www.health.qld.gov.au/directives/html/a.

Should you require any further information, Mr Michel Lok, General Manager, Community and Scientific Services, Health Support Queensland is available to assist and can be reached via email at [redacted] or on telephone [redacted]

Health Service Directive

Directive # <insert number here>
Effective Date: 22 July 2019
Review Date: 22 July 2022
Supersedes: New Directive

Caring for People Disclosing Sexual Assault

Purpose

This Health Service Directive requires Hospital and Health Services to take a consistent approach to managing the clinical and psychosocial needs of people who have experienced sexual assault. This includes the person-centred provision of forensic examinations.

Scope

This directive applies to all Hospital and Health Services (HHSs).

Principles

- Compassion – everyone disclosing sexual assault will be treated with respect, courtesy, compassion and dignity and their clinical care and any forensic examination will be responsive to their particular needs including access to, or referral to counsellors and support services.
- Person-centred care – everyone disclosing sexual assault will have access to trained clinicians who can provide timely and confidential clinical care and forensic examinations after presentation to hospital.
- Information – everyone disclosing sexual will be given clear information about their options relating to having a forensic examination and the level of involvement of police.
- Collaboration – HHSs will work effectively with the Queensland Police Service, other government agencies as well as community organisations to ensure a responsive, supportive and integrated approach to caring for people disclosing sexual assault.

Outcomes

Hospital and Health Services included in the scope of this directive shall achieve the following outcomes:

- Compliance with Queensland Government Interagency Guidelines for Responding to People Who Have Experienced Sexual Assault.
- Compliance with the Health Service Directive Guideline: Guideline for Management of care for Adults (14 years and over) Disclosing Sexual Assault

- Compliance with the Department of Health Guideline: Conducting Child Sexual Assault Examinations (*Document Number # QH-GDL-943:2015*)
- Compliance with the informed consent requirements detailed in the Queensland Health Guide to Informed Decision-Making in Healthcare

In doing so, HHSs will provide consistently high-quality, compassionate and person-centred services to people disclosing sexual assault who present to public hospitals.

Mandatory requirements

Hospital and Health Services (HHS) will:

- Provide 24-hour access to clinical care and forensic examinations for people 14 years and over disclosing a sexual assault in accordance with the Guideline for the Management of Care for Adults (14 years and over) Disclosing Sexual Assault.
- Ensure everyone who discloses that they are the victim of a sexual assault is informed of their choices about forensic examinations and reporting the assault to police, including the benefits of early reporting.
- Provide forensic examinations to victims of sexual assault when victims choose to have a forensic examination regardless of whether victims decide to report the matter to police or decide to defer this decision.
- Ensure adherence to informed consent for all aspects of caring for people disclosing sexual assault, including clinical treatment, forensic examinations, evidence collection and storage, police involvement, referrals and the release of information to third parties.
- Provide clear information about the storage, access and destruction of forensic examination samples to victims of sexual assault who have a forensic examination but choose to defer the decision to report the assault to police.
- Provide a suitable model of care for managing paediatric sexual assault patients (under 14 years of age) within each HHS.
- Report all suspected child sexual assaults to Child Safety Services in line with the mandatory reporting and duty of care responsibilities of clinicians.
- Ensure all patients are referred to (with patient consent) and/or provided information regarding sexual assault counselling and support services.

Approval date:

Issued under section 47 of the *Hospital and Health Boards Act 2011*

Definitions of terms used in this directive

Term	Definition / Explanation / Details	Source
Hospital and Health Service	Hospital and Health Services are statutory bodies and are the principal providers of public sector health services.	*Hospital and Health Boards Act 2011*
Forensic Examination	The forensic examination consists of obtaining a history as to the nature of the assault to guide the subsequent physical examination. It also includes interpretation of injuries and the collection of forensic samples as it relates to the alleged sexual assault. (A Sexual Assault Investigation Kit (SAIK) is used to collect DNA evidence)	Queensland Government Interagency Guidelines for Responding to People Who Have Experienced Sexual Assault.
Child	Under the age of 18 years For child victims of sexual assault, under the age of 14 years, sexual assault medical and forensic examinations should be performed by a medical officer with appropriate paediatric skills including child protection and/or sexual assault medical examination training or skills.	Department of Health Guideline: Conducting Child Sexual Assault Examinations (Document Number # QH-GDL-943:2015
Trained Clinicians	Forensic Examinations can be provided by: • Forensic Physician • Medical Officers who have received training in sexual assault examination • Senior Medical Officers accessing phone support from Clinical Forensic Medicine Unit • Government Medical Officers • Forensic Nurse Examiners (postgraduate qualification in Forensic Medicine) • Sexual Assault Nurse Examiners. Nurses trained in sexual assault examinations having completed a recognised short-course eg SANE 40CPD short course)

Email: [redacted]

Dear Mr [redacted]

Guideline for the Management of Care for People 14 years and over Disclosing Sexual Assault

In July 2019, Hospital and Health Services (HHS) were consulted on the Health Service Directive: Caring for People Disclosing Sexual Assault which was published with an effective date of 22 July 2019. There was a related guideline titled *Guideline for the Management of Care for Adults (14 years and over) Disclosing Sexual Assault* (the guideline).

Following further clinician consultation and in line with the principle of putting patients first, it is necessary to make changes to the guideline to clarify the management of care for patients aged 14 to 17 years. Specifically, the guideline has been revised to address choices for patients aged 14 to 17 years disclosing sexual assault who are competent to make decisions relating to reporting to police and having 'just in case' forensic examinations.

It is important to note that the changes will not impact on the workload of HHSs but will clarify management of care.

The guideline has been retitled to: *Guideline for the Management of Care for People 14 years and over Disclosing Sexual Assault.* In addition, it has been transferred to a Queensland Health guideline template as was the original intention. It will be published on the Queensland Health guideline page at https://www.health.qld.gov.au/qhpolicy.

Subject: thanks for Monday visit

Mark,

Thanks so much for your time on Mon – Melanie and Ashleigh really appreciated it and it was great for me to reconnect. Please pass on our thanks to Amanda as well.

I wanted to see if we could continue a conversation around toxicology specimens for so-called 'just in case' (JIC) forensic examinations.

The inability to collect toxicology samples and also clothing items (esp underwear) from complainants who are not yet ready to speak to police within the current JIC process means that the SAIK and the JICK processes are not the same. This can be difficult for complainants to understand when they are deciding which forensic examination pathway they want to pursue. As I understood your comments, it seems we may be able to include these samples for storage at FSS alongside biological forensic swabs?

I know of at least one sexual assault case involving this office that proceeded to trial but was initially a JIC forensic examination. Toxicology issues were raised by DPP at trial and could not be addressed appropriately because of the inability to include tox samples at the time of examination, so I do believe it is worth exploring.

I have cc-ed Lara because this matter was raised in recent discussions with the Womens Safety and Justice Taskforce committee, and may be important with respect to Justice McMurdo's recommendations.

I'm happy to meet to further discuss if/when suits,

Thanks
Cathy

For Laboratory: Potential forensic evidence "Just in Case" Forensic Examinations

Patients who have disclosed a sexual assault but are not ready to involve police can request a forensic examination "Just in Case" they decide to make a police complaint later.

Request & Delivery of Just in Case kits

Clinicians can obtain a Sexual Assault Investigation Kit customised for Just in Case (JIC SAIK) examinations from the local Pathology Queensland Laboratory.

- Each kit will include collection swabs, tamper evident bag, pathology request form and chain of custody form.

The sealed and completed kit will be hand delivered to the Pathology Queensland laboratory for immediate transport to Forensic and Scientific Services (as per Appendix C).

- Any other items should not be accepted by the laboratory, only the sealed bag of swabs.

Pathology request form – clinician to complete

A pathology request form will be placed in an envelope on the outside of the kit (see Appendix A).

When entering the form to ensure privacy **enter the unique bag ID (see Appendix A) as the patient Surname. The additional agreed forms of identification are the first name of the patient, the date of birth and sex. (see Appendix B).**

Chain of Custody Form (See Appendix D)

Relinquished by:

At every stage the person relinquishing the package must complete the chain of custody form with their name, section/unit/date/time and whether the tamper seal was intact and sign.

Received by:

At every stage the person receiving/processing the package must complete the chain of custody form with their name, section/unit/date/time and whether the tamper seal was intact and sign.

This chain of custody form must stay with the package at all times.

Laboratory processing in AUSLAB

Register sample in AUSLAB as per table below:

Sending samples to Forensic and Scientific Services

Where samples can be sent same day

1. Sample is to be sent cool to Forensic and Scientific Services in a **dedicated** category B esky as per QIS 24545.
2. Esky must be tracked through Diagnostic Esky Tracking program sending directly to SS.
3. Call TOLL on [redacted] (see Appendix C) to arrange a same day collection.

   Note the test code FORSS will automatically add this to a SS packing list. This sample must be placed on its own packing list. There must be no other specimens placed with this.

AUSLAB Clinical and Scientific Information System

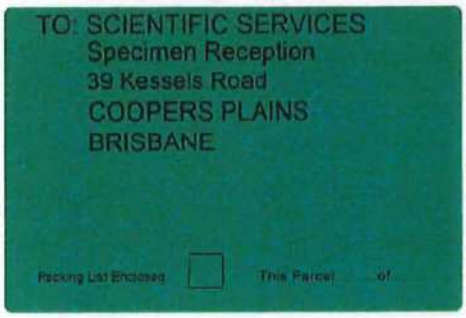
4. Place the GREEN "To scientific services" and the hot pink "Forensic Sciences" label on the esky.



5. Place a 'keep refrigerated' label on the outside of the esky.

Where samples cannot be sent same day

6. If sample cannot be sent the same day store sample in Freezer until it can be sent. Sign that the sample has been relinquished to the freezer and indicate the storage location on the chain of custody form (Appendix D).
7. When the sample is removed from the freezer for packaging the staff member must sign in the "received by" section.
8. Proceed as per step 1 above.

If a staff member opens the Tamper Evident Bag prior to sending to FSS

1. If the tamper evident bag is accidently opened, it must be resealed with tape, with a signature over the seal.
2. A specimen note must be placed in Auslab to detail that the tamper evident bag was accidently opened, that no items were removed or added and that the tamper evident bag was re-sealed. The date and time of the opening and re-sealing must be included in the specimen note and identified that if any other staff member observed the opening and re-sealing.
3. The opening of the tamper evident bag must be detailed on the Chain of Custody form, so that subsequent handlers of the tamper evident bag are aware that the bag was previously opened.

MALE GENITAL ANATOMY AND METHOD OF GENITAL SWAB COLLECTION

The following information is provided to assist with an understanding of male genital anatomy and sites of sample collection.

a) The **shaft** is the elongated part of the penis.

b) The **glans penis** is the 'cap-shaped' expansion at the end of the penis.

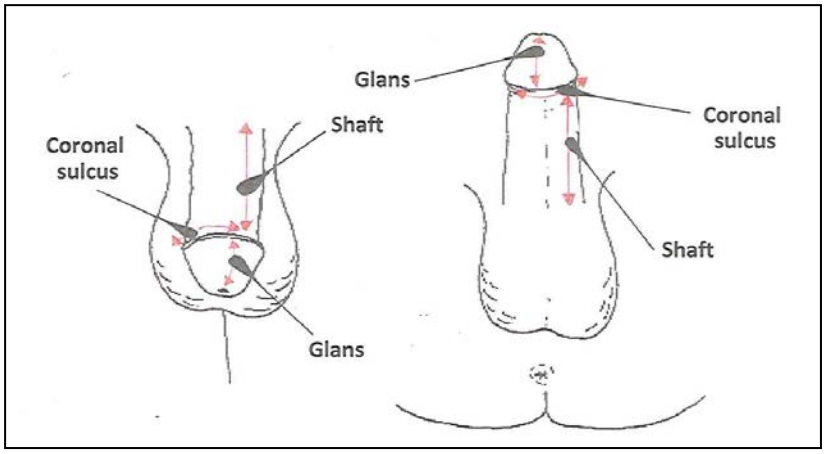
c) The **coronal sulcus** is the groove immediately underneath the corona of the glans penis, which is the rounded proximal border of the glans penis.

d) Each of the three areas described is swabbed twice;- firstly with a cotton swab moistened with sterile water, and secondly with a dry cotton swab. In an uncircumcised male, it is necessary to retract the foreskin to collect swabs from the glans and coronal sulcus.

   i. *Swabs from shaft:* whilst holding the tip of the penis so that all surfaces of the shaft are exposed, the swab is moved downwards along the length of the penis from the foreskin to the base of the penis near the scrotum. This is done 6-8 times at different sites to ensure that the majority of the shaft skin makes contact with the swab.

   ii. *Swabs from glans:* the swab is moved over the skin of the glans at 6-8 sites to ensure that the majority of the glans skin makes contact with the swab.

   iii. *Swabs from coronal sulcus:* the swab is moved along the skin circumferentially around the groove immediately beneath the corona of the glans penis.



e) At no time is a swab inserted into the urethra or 'urine passage' during this process.

Subject: RE: SAIK [redacted] Forensic Case File [redacted] Forensic Exhibit Number [redacted]

Hi Cathy,

Apologies for not replying sooner, I've been away for a few days. There's no need to attach this form to FPO samples, we can get all the relevant offence details from the police on their QP127 form.

Many thanks
Abbie

Abbie,

Rather than write the sample information out on the Magistrate's Order by hand, we've designed the attached form to accompany FPO samples given there is no designated FPO sample kit. Do you want us to attach the Order as well or will police provide it separately to you?

Cathy

This email originated from outside Queensland Health. DO NOT click on any links or open attachments unless you recognise the sender and know the content is safe.

The plan will be to use the new FMEK from Hazpak and dispense with a separate physical exam kit. We are getting new fingernail kits, as well, but this is being organised by Forensic Pathology (through Hazpak, as I understand)

Cheers, Maria

Maria
If you have to swab/sample offenders, do you have a special kit or just use same Hazpak one as for complainants.

Subject: SAIK swabs

Good Morning,

I am the acting Senior Scientist of the Evidence Recovery Team, Forensic DNA Analysis. We are the team who process sexual assault investigation kits (SAIKs) to test for bodily fluids and DNA. We have received a number of SAIKs recently that have a large number of internal swabs in them. I just wanted to contact you to gain more of an understanding of your rationale behind collecting so many vaginal swabs.

To give you an insight on our processes here, as per our agreement with the Queensland Police Service we examine every item contained within a SAIK individually, we do not selectively test swabs based on location or collection order. Each swab gets full presumptive screening for semen, including microscopy. We then process the swabs through our analytical section which is a costly process (semen positive swabs get split into two samples with the basic process costing on average $200-$300 per sample). In collecting multiple swabs from the same site this impacts examination time, turnaround times for the results, and potentially decreases the likelihood of getting a good result from any one swab, as any foreign cellular material present is diluted across multiple swabs. It is much better to concentrate the sample onto one swab. When we examine a large SAIK this also impacts on turnaround times for other cases.

A standard female SAIK usually consists of:
1 x high vaginal swab
1 x low vaginal swab
1 x vulval swab

1 x cervical swab (if the SAIK is collected >7 days after the offence)
1 x perianal swab (if case history suggests anal assault)
1 x rectal swab (if case history suggests anal assault)
1 x oral swab (if case history suggests oral assault)
Skin swabs if semen or saliva is suspected in other areas (wet and dry swabs for these areas is fine)

Of course every case is different and as the FMO it is at your discretion which samples you collect, I understand that the patient is your main priority and you must do whatever is in their best interest. If there is some justification behind collecting multiple swabs please indicate this on the accompanying SAIK paperwork.

If you need me to explain any of our processes further, or if you require any additional information please do not hesitate to contact me.

Kind regards
Abbie

Subject: Re: SAIK Issues from Laboratory

Good afternoon,

I am reaching out due to concerns received from the forensic laboratory with regards to sexual assault kits they have received from your practice.

The collection of multiple swabs from the same genital region is not supported by the laboratory. The laboratory has indicated:

- collecting multiple swabs from the same intimate / internal site yields little benefit with respect to increased recovery of forensically relevant information;
- the examination of swabs collected as part of a Sexual Assault Investigation Kit is a particularly labour intensive process, kits containing extra samples that are of limited benefit greatly add to the time taken to complete examinations AND
- this increases time and number of events of interpretation and reporting.

The collection of two swabs (wet and dry) from skin is acceptable.

I am aware the Faculty of Forensic and Legal Medicine in the UK has issued guidelines recommending multiple swabs. I am further aware they have provided an accompanying document "the evidence" which does not contain evidence supporting double swabbing of areas other than skin. The local RCPA guidelines do not mention multiple swabs of (particularly) the endocervix.

The laboratories concerns resonate and should be taken into account when considering your practice. If a basis exists for this practice it would need to be compelling: I would welcome you sharing it.

Kind regards,
Adam

Attachments: SAIK swab procedure FSS 2011.docx; SAIK swabs

Dear all,

I received the email below from Director CFMU last week. The issue re ideal number of swabs to be collected as part of SAIKs has been a long-running issue of debate.

I've attached an email I received back in 2016 from an FSS scientist RE THE ISSUE explaining their procedure - she acknowledges that the collection of swabs is at the clinician's discretion. I've also attached a summary of lab approach to SAIK swabs as explained to me in 2011 after the decision was made to cease making slides 'in the field'.

FSS's issue appears to be with collection of more than one swab from 'internal (mucosal)' sites (ie low vaginal, high vaginal, endocervical, rectal) with the taking of 2 swabs (wet and dry) from skin being acceptable. To my mind, this would mean 2 swabs from inner labial, peri-anal, anal sites is acceptable.

With respect to a non-skin site, if there is residual material remaining after first swab is collected, I believe (and guidelines acknowledge) that the clinician is justified in taking a second swab - we've been asked to record the reason for collection of a second swab on the SAIK paperwork.

Any comments/different ideas welcome – we can discuss together when everyone next in.

Cathy

Thanks Adam,

I appreciate that you feel that I have the authority, as Chief Examiner, to dictate what the Faculty guidelines should be with regard to this issue; however, this is not the case.

The purpose of the forensic examination is not limited to obtaining trace evidence, but includes the identification of injury. Emergency department staff are not forensically trained; their role is to identify medical conditions including injury, that require health intervention.

I would hope that a complainant would never be 'subjected' to an intimate procedure, and that these are only ever performed with fully informed consent. Delaying forensic examinations until the following day could equally be seen as subjecting a person to unnecessary emotional distress.

I suggested that rather than make changes that appear to differ significantly from other jurisdictions, we continue as is until the release of the Faculty guidelines, which I believe are not far off.

Subject: RE: DNA retention baseline protocol

Hi Cathy,

Just to bring this forward again as I believe it is important you explain further. I note Ian Home's comments and questions remain unanswered by you. I have included them below to assist you.

> *It is my understanding that the forensic examination is for the purposes of trying to obtain trace evidence. If the scientific research suggests the odds of detecting trace evidence outside of the time frames for emergent examinations that Adam put forward, is exceedingly unlikely if not zero, then why would we subject someone to an intimate procedure?*
>
> *Examinations should not be done as a therapeutic procedure or to placate anyone. Surely victims would be better off being medically cleared by ED staff and then counselled by social workers.*

If they still wish to pursue an examination or have injuries that the ED staff are for whatever reason uncomfortable documenting, then this can and should be done during business hours.

If you suggest any variations to the hours proposed, then please let us all know.

I note you have also not answered Kathy Robinson's very reasonable question and so have included it below as well:

My understanding is that our role as forensic medical officers is to attend to the "collection and documentation of medico-legal evidence ***where appropriate".*** *Is it not our ability to decide the appropriateness of the intimate examination (a decision based partly upon our knowledge of published data on DNA retention times), a component of what helps define us as a medical specialty?*

You provided a case example in your email: please provide what you would consider the appropriate response to a digital penetration greater than 15 hours after, and your basis.

In your role as chief examiner of the college, I feel that Ian and Kathy in particular would benefit from your response.

Kind regards,
Adam

Subject: RE: DNA retention baseline protocol

Thanks everyone for your responses,

Cathy, I appreciate the reactivation of the conversation to address your particular issues. Have you any suggestions regarding any alternate time frames?

These guidelines represent timely access. They have a basis in the ability to detect DNA substantially falls

and (importantly) plateaus after this time, remaining at a low level.

I note Ian Home's comments and questions remain unanswered by you and you could go some way to credibility by addressing them. I have included them below to assist you.

> *It is my understanding that the forensic examination is for the purposes of trying to obtain trace evidence. Subject: RE: DNA retention baseline protocol

Thanks Adam,

I acknowledge your reference to the ability to use our clinical acumen in relation to examination time frames but would comment that these guidelines are not in fact 'patient-centred'.

Timely access to forensic examination is a central principle of the healthcare response to sexual assault. Patient/complainants who are told to come back the next day or required to wait for a forensic examination unnecessarily, may be less likely to proceed with a complaint.

It could be argued that someone presenting to a police station or at an emergency department at say 11pm, reporting digital vaginal or anal penetration, or penile oral penetration that took place at 9am that day, should not be required to go home and come back, or sit in an emergency department until the next day for a forensic examination.

There is also the potential that delaying forensic examination until the next day will mean the examination then occurs outside recommended guidelines, reducing the likelihood of evidence retrieval.

Could this be a politically sensitive decision in relation to the CFMU response to sexual violence? Aside from necessary discussion around evidence retrieval and 'patient-centred' care, we need to be cognisant that recent history has shown that politics will ultimately drive our service delivery.

Thank you all again for those who contributed to the discussion.

I have only received positive comments. As such the information below will stand as our reference point.

I think we will look to revising this annually, with a similar call around.

Those who wish to provide an alternative standing point with some evidence basis: I only ask that you quote the relevant aspect of the reference basis when providing this.

I have copied in our kind administration staff here with the below table: could you please look to placing a review date of 1 May next year?

Many thanks,

Kind regards
Adam

Thanks for the contribution so far.

I apologise for the confusion around one entry in particular: not sure what happened there.

The principle element of this process is establishing the examinations we will perform out of hours. You will note I haven't set a maximum time for examination as I am well aware there are exceptional circumstances that can arise. Instead, the important note is the likely 'plateau' noted with regard to the chance of detecting DNA after a period of time such that there is no advantage in an emergent examination.

I believe this is different to the stated intention of the FFLM document around DNA retention alone and instead represents a practical and consistent response to our stakeholders such that they do not have inconsistent expectations. Minority cases/exceptional n

The absence of a maximum level should not be seen as a need to eliminate clinical judgment. Subjecting a person to an intimate examination greater than 7 days following an assault would have to have a legitimate basis to satisfy the ethical considerations of subjecting patients to unnecessary testing.

ıre of Assault	Acute examination (regardless time of day)	Non-Acute examination (8am to 1700hrs)
tal penetration: ina	12hrs	>12hrs

tal penetration:	12hrs	>12hrs
penetration	6hrs	>6hrs
inal penetration	72hrs	>72hrs

Thanks Cathy,

Apart from the document being long and "busy" to look at, the references cited are problematic if not confusing. A lot of them are still quite dated such as Allard; and many of the other references do not support longevity of spermatazoal survival in areas such as anus and mouth (reading the short abstracts provided). The Y-STR stuff might be more promising but until such a time as we are using these techniques in our jurisdiction I can't see the utility of testing days down the track for such cases, particularly when we are talking to emergent responses (specifically out-of-hours). I guess these are the controversies that will drive the discussion and confound the practice of CFM (specifically the domain of SA examination).

One would hope that the RCPA research this thoroughly, using current and relevant references and do not 'cut-and-paste' the English model.

Gary

Thanks for starting this discussion off Adam.

Attached are the FFLM UK recommendations which may be worth adding to your attachments; these are referred to by many sexual assault services nationally in the absence of an equivalent RCPA FCFM document at this time.

It's anticipated that the FCFM will develop a similar standard document for Faculty Fellows in the near future.

I will send through any other references that may be of assistance.

Hi Ally,

T'was that not an exceptional case – lying flat on their back in ICU following the incident? A good example of the need for clinical judgement rather than rigid timeframes!

I hear 24 hours, I hear 72 hours, any advances? Going, going....sold to the person with the swab in their hand!

Hi All,

I agree we need a standardised window for both acute and non-acute examinations. If an acute examination is done later than the agreed time, the examiner should be able (and expected) to provide an explanation for their clinical decision.

I note you left out a time for anal penetration – I'm guessing 24 hours for acute examination? The other important element is the cut-off for not performing an examination. Below is the table I used for an assignment last year....

Sample site	**Time frame for collection**
Mouth	Semen – 24hr
Skin	Epithelial cells – 12hr Bodily fluids – 48hrs
Vulval, external labia	Digital penetration – 12hr Cunnilingus – 24hr Intercourse – 5 days
Low vaginal, high vaginal, cervical	Intercourse – 5 days
Perianal, anal, rectal	Digital penetration – 12hr Intercourse – 2 days
Penile	Bodily fluids – 3 days
Fingernails	Trace evidence – 48hr
Toxicology: Blood	48hr
Urine	48hr; 5 days if drug-facilitated assault

Subject: DNA retention baseline protocol

Good morning,

A few recent experiences have seen the need for consistency of expectation from requesting detectives regarding timelines for sexual assault examination. The timeframes in which we conduct forensic examinations should be shared with all investigating officers such as they are not disappointed should they be told something they were not expecting. In most cases detectives would expect a SAIK would be done in the course of an investigation and, also in most cases, this is true! There are exceptions informed through research, publications and (where such are not available) an attempt at consensus.

It is important to understand these as we do not wish to subject individuals to unnecessary intimate examination. It is also important that they do not have false expectations.

As a result I am circulating the below table for consultation. Please let me know what you think, and whether any additions are required.

I have thrown on a couple of newish references as opposed to Allard, which is still heavily referenced!

I know there was a recent Australian publication looking at variability between jurisdictions, but not really providing advice.

Y-STR segment testing will also certainly influence this should it be introduced here.

Kind regards
Adam

Thank you all again for those who contributed to the discussion.

I have only received positive comments. As such the information below will stand as our reference point.

I think we will look to revising this annually, with a similar call around.

Those who wish to provide an alternative standing point with some evidence basis: I only ask that you quote the relevant aspect of the reference basis when providing this.

I have copied in our kind administration staff here with the below table: could you please look to placing a review date of 1 May next year?

Many thanks,

Kind regards
Adam

Thanks for the contribution so far.

I apologise for the confusion around one entry in particular: not sure what happened there.

The principle element of this process is establishing the examinations we will perform out of hours. You will note I haven't set a maximum time for examination as I am well aware there are exceptional circumstances that can arise. Instead, the important note is the likely 'plateau' noted with regard to the chance of detecting DNA after a period of time such that there is no advantage in an emergent examination.

I believe this is different to the stated intention of the FFLM document around DNA retention alone and instead represents a practical and consistent response to our stakeholders such that they do not have inconsistent expectations. Minority cases/exceptional n

The absence of a maximum level should not be seen as a need to eliminate clinical judgment. Subjecting a person to an intimate examination greater than 7 days following an assault would have to have a legitimate basis to satisfy the ethical considerations of subjecting patients to unnecessary testing.

Nature of Assault	Acute examination (regardless time of day)	Non-Acute examination (8am to 1700hrs)
Digital penetration: Vagina	12hrs	>12hrs
Digital penetration: Anal	12hrs	>12hrs
Oral penetration	6hrs	>6hrs
Vaginal penetration	72hrs	>72hrs
Anal penetration	72hrs	>72hrs
Skin swab: Semen	24hrs	>24hrs
Skin swab: Saliva	24hrs	>24hrs

Kind regards,
Adam

Thanks Cathy,

Apart from the document being long and "busy" to look at, the references cited are problematic if not confusing. A lot of them are still quite dated such as Allard; and many of the other references do not support longevity of spermatazoal survival in areas such as anus and mouth (reading the short abstracts provided). The Y-STR stuff might be more promising but until such a time as we are using these techniques in our jurisdiction I can't see the utility of testing days down the track for such cases, particularly when we are talking to emergent responses (specifically out-of-hours). I guess these are the controversies that will drive the discussion and confound the practice of CFM (specifically the domain of SA examination).

One would hope that the RCPA research this thoroughly, using current and relevant references and do not 'cut-and-paste' the English model.

Gary

Thanks for starting this discussion off Adam.

Attached are the FFLM UK recommendations which may be worth adding to your attachments; these are referred to by many sexual assault services nationally in the absence of an equivalent RCPA FCFM document at this time.

It's anticipated that the FCFM will develop a similar standard document for Faculty Fellows in the near future.

I will send through any other references that may be of assistance.

Cathy

Hi Ally,

T'was that not an exceptional case – lying flat on their back in ICU following the incident? A good example of the need for clinical judgement rather than rigid timeframes!

I hear 24 hours, I hear 72 hours, any advances? Going, going....sold to the person with the swab in their hand!

Hi All,

I agree we need a standardised window for both acute and non-acute examinations. If an acute examination is done later than the agreed time, the examiner should be able (and expected) to provide an explanation for their clinical decision.

I note you left out a time for anal penetration – I'm guessing 24 hours for acute examination? The other important element is the cut-off for not performing an examination. Below is the table I used for an assignment last year….

Sample site	Time frame for collection

Mouth	Semen – 24hr
Skin	Epithelial cells – 12hr Bodily fluids – 48hrs
Vulval, external labia	Digital penetration – 12hr Cunnilingus – 24hr Intercourse – 5 days
Low vaginal, high vaginal, cervical	Intercourse – 5 days
Perianal, anal, rectal	Digital penetration – 12hr Intercourse – 2 days
Penile	Bodily fluids – 3 days
Fingernails	Trace evidence – 48hr
Toxicology: Blood	48hr
Urine	48hr; 5 days if drug-facilitated assault

Subject: DNA retention baseline protocol

Good morning,

A few recent experiences have seen the need for consistency of expectation from requesting detectives regarding timelines for sexual assault examination. The timeframes in which we conduct forensic examinations should be shared with all investigating officers such as they are not disappointed should they be told something they were not expecting. In most cases detectives would expect a SAIK would be done in the course of an investigation and, also in

most cases, this is true! There are exceptions informed through research, publications and (where such are not available) an attempt at consensus.

It is important to understand these as we do not wish to subject individuals to unnecessary intimate examination. It is also important that they do not have false expectations.

As a result I am circulating the below table for consultation. Please let me know what you think, and whether any additions are required.

I have thrown on a couple of newish references as opposed to Allard, which is still heavily referenced!

I know there was a recent Australian publication looking at variability between jurisdictions, but not really providing advice.

Y-STR segment testing will also certainly influence this should it be introduced here.

VICTORIAN INSTITUTE OF FORENSIC MEDICINE

Information: Recommended Maximum Time for Routine Forensic Sample Collection

Site (on Victim)	Nature of physical contact	Time since last contact unwashed	Time since last contact if cleaned/altered
1. Around mouth	Penile-oral penetration, kissing	72 hours	NA if washed
2 (a) swabs from inside mouth and, 2 (b). mouth rinsings	Penile-oral penetration	24 hours	NA if drank / ate / cleaned teeth
Vaginal vestibule, vulva	Penile, oral, digital or other skin contact with the vulva or vaginal vestibule	72 hours	NA if washed
Vaginal canal and cervix	Penile - vaginal penetration	1 week (7 days)	Note no reduction if history of washing or menstruation
	Digital -vaginal penetration with no other body fluid transferred from assailant	72 hours	Note no reduction if history of washing or menstruation
Anus	Penile, oral, digital or other skin contact with the anus	72 hours	Note no reduction if history of washing
Skin to skin contact not listed above	Oral, digital (or other skin) or biological fluid contact with victim's skin	72 hours	NA if washed
Penile swab (no slide)	After penetrating any orifice or digital (or other skin)-penile contact. NB: The VPFSC does not identify cell types or the anatomical area of origin of any foreign DNA found.	72 hours	NA if washed
Fingernail scrapings	Eg., Scratched skin Digital penetration vagina and anus	72 hours	NA if washed

NA: Not Applicable - do not collect samples from this site unless exceptional circumstances exist

There is no upper time limit for collection of biological samples such as foreign hairs, foreign material such as ejaculate in hair, and objects such as condoms or stained (or possibly stained) clothing such as underwear but consider actions of complainant and factors that might reduce utility of sample.

Collect underwear or other items of clothing when fluids might have drained onto clothing or genital skin (including a penis) might have transferred DNA to clothing.

>>> On 07/12/2009 at 1:10 pm, in message <[redacted]>,
Catherine Lincoln wrote:

Bob,

With respect to the issue of no longer needing to make slides from swabs, have we had a written lab directive re that? My recollection was that when the issue of stopping making slides was last explored a few years ago, there was some question as to whether the making of a slide from a dried swab at an unspecified time after the examination may compromise the quality of the slide which as I understand it, is the crucial part of the lab's analysis process (ie swab only looked at if microscopy +ve).

I think a number of senior scientists from other States were canvassed about the idea and had reservations. I actually wrote a protocol for a simple lab study that would have proved or disproved this view, but it but it never got off the ground.
I would be very happy not to have to makes slides as slide labelling is a particularly onerous part of the process.

While we're on this subject, could we please re-visit (!) the issue of some sort of basic analysis results coming back to the examining doctor, at least so we can get some idea of the quality of our samples. Working in the current 'vacuum' that we do, we have no way of knowing whether our current practices pick up any DNA at all, let alone whether they are contaminated or not.

Subject: Re: Cleaning of Forensic rooms - URGENT

Hi Cathy,

The process we follow to clean the forensics rooms is as follow:

Our cleaner puts on the appropriate PPE (disposable gown, gloves, goggles, head cover, N95 mask). They bring their cleaning trolley but leave it outside the room.

They then proceed inside the room, wipe all surfaces (inc desks, doors and handles etc...) with microfiber cloths and divercleans which is a hospital grade bleach.

They use a special handle and cleaning cloth to wipe the walls with divercleans. if required we change the disposable curtains.

Finally the floor is mopped thoroughly with divercleans as well, upon exit the room. The door is then locked behind us.

We sign the different registers provided to ensure our staff and your team have a record of their entry into the room.

As you can see we only use one chemical called divercleans (bleach) and a range of microfiber cloths and mops.

I hope this helps.

Please let me know if you need any further information.

Cheers,

David Dumaine

GUIDELINES FOR DNA CONTAMINATION MINIMISATION

Updated 14072019

Forensic examinations which include collection of forensic samples for DNA analysis are performed at the following facilities:

- Gold Coast University Hospital forensic examination room *(MAU; dedicated)**
- Logan Hospital forensic examination room *(ED; dedicated)**
- Robina Hospital forensic examination room *(ED Fast-Track; not dedicated)**
- Southport watch house medical room
- Logan District watch house medical room

* Before use of hospital forensic examination rooms, check room entry register/log to confirm that room has been terminally cleaned by hospital cleaners since last examination. Disposable curtains if in use, should be changed weekly.

1. If required to do a forensic examination immediately following another examination (complainant, suspect, prisoner) without showering or change of clothes; wash hands thoroughly at site of first examination; at second examination site 'double-glove' (sterile), put on blue DNA suit, then remove outer set of sterile gloves and perform examination wearing inner set of sterile gloves (+/- others as needed).

2. Use disposable paper sheet and gown packs provided.

3. Use sterile plastic drapes for all trolley and bench top surfaces (after decontamination cleaning).

4. Use disposable items where possible (pens, rulers, scissors). When not possible, plastic wrap or bleach-sterile water wipe items pre- and post-use (for example, light handle, camera, torch, magnifying glass).

5. Changing gloves is an important means of avoiding contamination; a new set of gloves should be used for (at least) each of the following components of the pre-examination cleaning and examination process:

   - **Decontamination cleaning of trolley and bench top surfaces (non-sterile)**
   - **Setting up items for examination and making bed with disposable sheet pack (sterile)**
   - **Collecting clothing items (sterile)**
   - **General physical examination (non-sterile if not sampling; sterile if sampling)**
   - **Genito-anal examination (sterile; consider 'triple-glove')**
   - **Labelling and sealing samples (sterile)**

   Change gloves more often as needed (for example, if collecting specimens that leave residue on gloves or selecting more equipment from storage)

6. Suggested process:

DECONTAMINATION CLEAN

1. **Wearing gloves, protective apron and shoe covers, wipe the following areas with 0.5% bleach wipes *(PDI Sani-Cloth CHLOR)*;**
   a. **Examination trolley surface and drawer handles**
   b. **Bench tops**
   c. **Examination bed and pillow**
   d. **Chairs/stool**
2. **Discard used wipes.**
3. **Leave surfaces for 3-5 minutes**
4. **Remove residual bleach from all wiped surfaces using low-lint towels *(Surgi-Dry)* moistened with sterile water for injection (single use 100ml bottles), then discard used wipes.**
5. **Change gloves.**

SETTING UP FOR EXAMINATION

6. **Open sterile plastic drapes and place on examination trolley and bench tops.**
7. **Place sterile sheets/pillow slip/gown on examination bed.**
8. **Empty contents of SAIK onto examination trolley top; add any additional swabs, and other items likely to be needed during examination (speculum, anoscope etc).**
9. **Change gloves.**

COLLECTION OF CLOTHING (and blue DNA SUIT if worn by subject)

10. **Place individual clothing items into separate paper bags as appropriate.**
11. **Provide paper gown to wear.**
12. **Change gloves.**

GENERAL BODY EXAMINATION

13. **Use non-sterile gloves to examine subject's body generally, take notes and photographs.**
14. **Use sterile gloves if taking any forensic samples during general physical examination (mouth, breast, neck).**
15. **Change gloves.**

GENITO-ANAL EXAMINATION

16. **'Double' or 'triple' glove (sterile) to prepare swabs and perform genito-anal examination and sampling; this allows removal of gloves as necessary during process (for example, new gloves for swab preparation; genital examination; anal examination).**
17. **Remove gloves.**

SEALING AND LABELLING SAMPLES

18. **Wear new set sterile gloves to seal and label swabs/samples**
19. **Post-examination; wipe trolley, bench tops and examination bed with 0.5% bleach wipes *(PDI Sani-Cloth CHLOR)* and sterile water moistened low lint wipes; discard used wipes.**

NOTE: Gloves not necessary to write up notes, referral letters, hand over sealed kits to police etc.

Technical Specification

Product Details	
Product name	Sani-Cloth Chlor +1000 Canister 50 F/Free × 6 (CE)
Product Code	XP00309C01
VJT Code	VJT315

Intended Use:

Sani-Cloth Chlor is a pre-moistened, ready to use low lint chlorine wipe for disinfection and decontamination of non invasive medical devices. Sani-Cloth Chlor is a non-sterile single-use wipe containing the active ingredient, sodium hypochlorite.

Instruction for Use

Sani-Cloth Chlor is contraindicated for use as a terminal sterilant /high level disinfectant on any surface or instrument that is a)introduced into the body or b) may come into contact with the bloodstream, including broken skin or mucous membranes.

Sani-Cloth Chlor can be used to pre-clean or decontaminate non invasive medical devices prior to sterilisation or high level disinfection.

Caution:

Avoid contact with eyes, skin or clothing. Wear protective gloves whilst using wipes. Wash thoroughly with soap after handling. Discontinue use if irritation and redness develops. Do not use with ammonia or acids. Keep lid closed and store upright in a cool dry place.

Regulatory Classification	
CE marked – 93/42/EEC	Yes

How to use...
Sani-Cloth® Chlor

1 Before you start always wear gloves and an apron.

2 Refer to CoSHH sheet, label instructions and 'Use by' date.

1M AFTER OPENING

3 Fill date and details on label (add 30 days onto the day it is opened to get 'Use by' date).

Date opened-
Use by date-

4

5 VISIBLY CLEAN ? VISIBLY SOILED

Remove any visible soiling with first wipe before using additional wipes.

6

7 For 1 application use 1 wipe and follow this wipe direction.

8

Recommended surface area coverage 1m square.
Allow disinfectant to dry on surface- Contact time.

Dispose of used wipe into clinical waste.

DO'S ✓

- Check 'Use by' date on label before use.
- Pull wipe away from you when dispensing from canister.
- Close lid after dispensing.
- Keep wipes close to areas of risk by means of bracket.
- Store upright in a cool dry place.
- Dispose of wipes into clinical waste.
- Avoid contact with the skin, eyes & clothes.
- Use one wipe for the prescribed area to ensure contact time.
- Wash hands with soap&water after handling.
- Use in a well ventilated area.

DON'TS ✗

- Single use wipes only... do not re-use or over-use them.
- Avoid wipe contact with ammonia or acids.
- Not for use on soft materials, fabrics or lenses.
- Never flush or dispose of wipes in a macerator.

Australian Register of Therapeutic Goods Certificate

Issued to

Thermo Fisher Scientific Australia Pty Ltd

for approval to supply

Thermo Fisher Scientific Australia Pty Ltd - Medical device cleaning/disinfecting wipe

ARTG Identifier	227283
ARTG Start date	27/08/2014
Product Category	Medical Device Included Class IIb
GMDN	58077
GMDN Term	Medical device cleaning/disinfecting wipe
Intended Purpose	A pre-treated fabric intended to wipe clean and disinfect the surfaces of medical devices and equipment between each patient use. The fabric is impregnated with a solution made of detergent(s) and antimicrobial agent(s) and is designed to help reduce the amount of dirt and microbial contamination on the surfaces of a medical device and equipment.

Manufacturer Details	Address	Certificate number(s)
Nice-Pak International Ltd	Aber Park FLINT, FLINTSHIRE, CH6 5EX United Kingdom	DV-2013-MC-07969-1

ARTG Standard Conditions

The above Medical Device Included Class IIb has been entered on the Register subject to the following conditions:

- The automatic conditions applicable to the inclusion of all kinds of medical devices in the Register are as specified in section 41FN of the Therapeutic Goods Act 1989.,
- The standard conditions that are imposed under section 41FO of the Therapeutic Goods Act 1989 when kinds of medical devices are included in the Register are as set out in the following paragraphs.,
- For a medical device included in the Register under Chapter 4 and imported into Australia, the Sponsor must ensure that information about the Sponsor is provided in such a way as to allow the sponsor to be identified.,
- Each sponsor shall retain records of the distribution of all of the sponsor's medical devices included in the Register under Chapter 4. In the case of records relating to a Class AIMD medical device, Class III medical device, or Class IIb medical device that is an implantable medical device, the distribution records shall be retained for a minimum period of 10 years. In the case of records relating to any other device, the distribution records shall be retained for a minimum period of 5 years.,
- The sponsor of a medical device included in the Register under Chapter 4 shall keep an up to date log of information of the kind specified in Regulation 5.8.,
- It is a condition of inclusion in the ARTG that the sponsor of a medical device that is an AIMD, Class III or implantable Class IIb provides three consecutive annual reports to the Head of the Office of Product Review, Therapeutic Goods Administration following inclusion of the device in the ARTG (as specified in 5.8 of the regulations). Annual reports are due on 1 October each year. Reports should be for the period 1 July to 30 June. The first report following the date of inclusion in the ARTG must be for a period of at least six months but no longer than 18 months. Subsequent reports are to be provided on 1 October for a further 2 years. The annual report must include all complaints and adverse events received by the manufacturer relating to problems with the use of the device that have been received by them over the year. For orthopaedic implant prosthesis that have been re-classified from Class IIb to Class III medical devices, annual report information must be submitted if the device meets either of the following criteria: I.The device was subject to a TGA application audit based on revision rate when the device transitioned from Class IIb to Class III; and/or II.No devices were supplied to the Australian marketplace before 30 June 2012. As per the standard automatic condition, annual reports should be submitted each year for the first three years of inclusion as a Class III medical device on the ARTG.,

- Where a medical device included in the Register, contains a substance which is included in the Fourth Schedule to the Customs (Prohibited Imports) Regulations or the Eighth Schedule to the Customs (Prohibited Exports) Regulations the Sponsor shall, at the time of importation or exportation of the medical device, be in possession of a licence and a permission for importation or exportation of each consignment of the goods as required by those regulations.,
- A sponsor shall ensure that a medical device within their control is stored and transported in accordance with the instructions and information provided by the manufacturer.

Products Covered by This Entry

1. Medical device cleaning/disinfecting wipe

Subject: Re: PDI Sani Cloth

Hi Cathy,

We have receive confirmation from PDI the chlorine component consists of 0.54% sodium hypochlorite.
It appears as though your calculation yesterday has been confirmed by PDI.

Is this sufficient conformation for you?

I have also provided Kate Hahn a sample of the Chlor Wipe canister and also the wall mount bracket.

Lorraine,

Sorry for delay in response – I've been off with hideous flu for a week.

I don't know anything about a SAIK register at LCH.

We have one here at our Southport office to record any we use – this register was started about a year ago to address use of 'old' kits that we had at the CFMU office and some hospitals.

If you're trying to trace a particular kit, Debbie could look it up for you if you give her a number.

Cc: Burkin.LorraineA[SER] [redacted]
Subject: SAIK - please read

Good afternoon all,

I attended LCH today to replenish the number of Sexual Assault and Investigation Kits held in the secure police storage unit at A&E. A register that was held in the storage unit appears to have now gone 'missing'? I will endeavor to have the register replaced at the hospital by Monday. (Unless anyone can shed any light on its whereabouts?). It is imperative that a register is maintained to ensure accountability of the kits being utilised. Distribution of the kits is currently under review by the Child Safety & Sexual Crime Group.

There are 2 further kits held in the storage cupboard at Logan CAIU. There was an investigation this past week that required investigators to attend Lady Cilento Hospital for a medical examination to be conducted. This hospital does not have local arrangements with Police to have SAIK stored at the hospital. Spare kits will be held at Logan CAIU in the event investigators are required to attend hospitals outside our district. Again, please maintain the register that is held with these kits.

In addition, a recent Sexual Violence Liaison Officer meeting I attended with counsellors at the Centre Against Sexual Violence Woodridge has revealed a significant decrease in QPS referrals for victims of sexual assault.

The emotional support of rape complainants is of particular importance and it is highly desirable that such support and counselling is made available at as early a stage as possible after initial complaint. Such support is can be provided by **The Centre Against Sexual Violence** for females aged 12 years and over and can be

contacted on the following phone number: business hours: [redacted] Information pamphlets are displayed in the waiting room at Logan CAIU. For staff at outside stations, please see me if you require further material.

If you have any issues, please contact me.

Regards,
Maria ORESGANIN

Hi Debbie

Apologies for taking so long, but when I was at your office the other week you were talking about the exam kits needed in order to conduct assault examinations.

I have done some research and there are Sexual assault identification kits, supplied by the FSS DNA Analysis team on [redacted] (I have attached a photo).

The nurses at Metro order the kits from FSS and they are delivered to the office.

Hope that assists.

SAIK swab procedure FSS since cessation of slide in field (2011)

Preparation of slide from swab:

- Cut piece of swab tip, place in tube and add liquid
- Agitate
- Place a droplet of fluid mixture onto slide (150µl)
- Heat fix and stain (HHE)

Examine slide (microscopy)

If see sperm, the remining part of the swab and any others are sent to the DNA lab for analysis

In the DNA lab:

- Differential lysis process to separate epithelial fraction from sperm fraction (in a male sexual assault of female, epithelial fraction mostly female DNA but may include some male DNA)
- Both fractions are analysed for a DNA profile (run through *Profiler Plus*)
- Compare results with reference DNA profile

Subject: SAIK swabs

Good Morning,

I am the acting Senior Scientist of the Evidence Recovery Team, Forensic DNA Analysis. We are the team who process sexual assault investigation kits (SAIKs) to test for bodily fluids and DNA. We have received a number of SAIKs recently that have a large number of internal swabs in them. I just wanted to contact you to gain more of an understanding of your rationale behind collecting so many vaginal swabs.

To give you an insight on our processes here, as per our agreement with the Queensland Police Service we examine every item contained within a SAIK individually, we do not selectively test swabs based on location or collection order. Each swab gets full presumptive screening for semen, including microscopy. We then process the swabs through our analytical section which is a costly process (semen positive swabs get split into two samples with the basic process costing on average $200-$300 per sample). In collecting multiple swabs from the same site this impacts examination time, turnaround times for the results, and potentially decreases the likelihood of getting a good result from any one swab, as any foreign cellular material present is diluted across multiple swabs. It is much better to concentrate the sample onto one swab. When we examine a large SAIK this also impacts on turnaround times for other cases.

A standard female SAIK usually consists of:
1 x high vaginal swab
1 x low vaginal swab
1 x vulval swab

1 x cervical swab (if the SAIK is collected >7 days after the offence)
1 x perianal swab (if case history suggests anal assault)
1 x rectal swab (if case history suggests anal assault)
1 x oral swab (if case history suggests oral assault)
Skin swabs if semen or saliva is suspected in other areas (wet and dry swabs for these areas is fine)

Of course every case is different and as the FMO it is at your discretion which samples you collect, I understand that the patient is your main priority and you must do whatever is in their best interest. If there is some justification behind collecting multiple swabs please indicate this on the accompanying SAIK paperwork.

If you need me to explain any of our processes further, or if you require any additional information please do not hesitate to contact me.

Kind regards
Abbie

Abigail Houlding

Sexual Assault Examination Time Frame

Consideration of DNA Retention Data to Guide Emergent Response

Nature of Assault	Acute examination (regardless time of day)	Non-Acute examination (8am to 1700hrs)
Digital penetration: Vagina	12hrs	>12hrs
Digital penetration: Anal	12hrs	>12hrs
Oral penetration	6hrs	>6hrs
Vaginal penetration	72hrs	>72hrs
Anal penetration	72hrs	>72hrs
Skin swab: Semen	24hrs	>24hrs
Skin swab: Saliva	24hrs	>24hrs

This remains a guide, and clinical acumen may be applied as regards a maximum response time. This is to assist in a consistent, patient focussed response while allowing appropriate utility of the Forensic Clinician resource.

Review Date: May 1 2018

CURRICULUM VITAE: Catherine Ann LINCOLN *(updated Sept 2022)*

EDUCATION AND QUALIFICATIONS

2018	Associate Fellowship Royal Australasian College of Medical Administrators (AFRACMA)
2014	Foundation Fellowship of the Faculty of Clinical Forensic Medicine (FFCFM), Royal College of Pathologists Australasia (RCPA)
2013	PhD, Emergency Medicine (Forensic Medicine) University of Western Australia
2013	Fellowship of the Faculty of Forensic and Legal Medicine (FFLM), Royal College of Physicians, United Kingdom
2006	Forensic Toxicology Unit, Monash University
2002	Master of Forensic Medicine, Monash University
1987	MBBS, University of Western Australia

CURRENT POSITION

October, 2018-present

Director
Forensic Medicine, Emergency Department
Gold Coast University Hospital
Gold Coast Hospital and Health Service (GCHHS)

MEMBERSHIPS

Foundation Fellowship of Faculty of Clinical Forensic Medicine (FCFM), Royal College of Pathologists Australasia (RCPA)

- Faculty Committee member (2014-present)
- Chair, Curriculum Development Committee (July, 2015-2018)
- Chief Examiner FCFM, RCPA (2016 – present)
- RCPA Board Education and Assessment (BEA) member (2016 – present)

Fellowship of Faculty of Forensic and Legal Medicine (FFLM), Royal College of Physicians, United Kingdom

Australian Association of Forensic Physicians (AAFP) **no longer in existence; ceded to RCPA Faculty CFM*

- Foundation member
- Committee member and Education Officer (2009-2015)

Medico-Legal Society of Queensland (MLSQ) (2015-present)

Forensic and Medical Sexual Assault Clinicians Australia (FAMSACA)

- Member (2005- present)

Australasian College of Legal Medicine (FACLM)

- Fellow (2003-2022)
- Council member (from 2005 to 2009)

National Adult Sexual Assault Medical Committee (NASAMC) **no longer in existence; ceded to FAMSACA*

- WA representative from 1998-2003

Australian and New Zealand Forensic Medicine Society (ANZFMS)

- Council member 2004-2006

Australian Medical Association

20 September 2022

- Registration Number 8044

United Kingdom 1990-1994 (currently inactive)

MEDICAL DEFENCE

Medical Defence Association (MDA)

PROFESSIONAL BACKGROUND

October 2018 – current	Director Forensic Medicine, Emergency Department Gold Coast University Hospital
July 2005 – October 2018	Deputy Director Clinical Forensic Medicine Unit (CFMU) South East Region (SER), Queensland Health Support Queensland
May 2004 – July 2005	Acting Deputy Director Clinical Forensic Medicine Unit (CFMU) SER Responsibility for the provision of forensic medical services in the South East Queensland Region (Gold Coast and Logan).
Jan – May 2004	Forensic Medical Officer Clinical Forensic Medicine Unit (CFMU), Gold Coast
Dec 2003 – 2012	Part-time PhD student University of Western Australia (UWA) School of Primary Aboriginal and Rural Health Care Discipline of Emergency Medicine
Aug – Dec 2003	Full-time PhD student University of Western Australia (UWA) NHMRC Scholarship School of Primary Aboriginal and Rural Health Care Discipline of Emergency Medicine
1995 – Aug 2003	Director Medical and Forensic Services Sexual Assault Resource Centre (SARC) Perth, WA Responsibility for the running of the 24 hour crisis medical/forensic service for victims of sexual assault. This position involves the supervision of up to 10 doctors and participation at executive level within the organisation (part-time position with after hours on-call duties)
2002 – 2003	Sexual Health medical officer Infectious Diseases and Sexual Health Clinic Fremantle Hospital, WA.
1998 - 2000	Part-time General Practitioner Parry St Family Practice (a three doctor general practice) Fremantle, WA.
1993 - 1995	Sessional medical officer with on-call duties Sexual Assault Resource Centre (SARC) A 24 hour crisis medical/forensic service for victims of sexual assault in Perth, WA.
1994 - 1998	Part-time General Practitioner Canning Medical Centre (a four doctor general practice) Fremantle, WA.

[redacted]

20 September 2022

1992 - 1993	Trainee General Practitioner Kimbolton Medical Centre, Cambridgeshire, UK A year as trainee GP in a five doctor rural general practice servicing an area of 150 sq miles and providing care to approx 5000 patients. The position involved after hours on-call duties.
1992-1993	Sessional medical officer, Almond Rd Family Planning Clinic St Neots, Huntingdon, Cambridgeshire.
1991 - 1992	Sessional medical officer Regents Park Clinic for Sexually Transmitted Diseases A private STD/HIV clinic in inner London.
1987 - 1992	Various resident medical officer and senior house officer positions in Western Australia and United Kingdom.

TEACHING

Queensland (2004- present)

Chief Examiner, Faculty Clinical Forensic Medicine (RCPA); inaugural curriculum development (2015-present), inaugural examination coordinator (2021)

QPS Detective training ISACURE sexual offence investigation course, Brisbane 2021-2022

RCPA Sexual assault in Forensic Pathology, four 2 hr training mannequin workshops in Qld, SA, NSW, WA. (2013-2015)

Training, supervision and peer support Forensic Medical Officers since 2007

Emergency nurses in Watch houses program, GCUH WHEN program; orientation training (2013-present)

Griffith University

- Senior Lecturer, Griffith University Medical School (2005-present)
- Medical student Year 4 Coordinator Elective/Selective co-placement with Forensic Pathology (2010-2015)
- Medical student Year 4 CLEIMS Understanding the Coronial Process (2015)
- Medical students Year 3 Structured Clinical Instruction Model (SCIM) sessions *'Introduction to Clinical Forensic Medicine'* (2006-2009)
- Medical student clinical community placement supervision Year 1 (*Health in the Community)* to Gold Coast CFMU (2005-present)
- Master of Legal Medicine, Course Lecturer (2006)

Bond University

- Medical students (Year 3), *'Medicolegal aspects of Domestic Violence'* (2007)

GCHHS and Logan Emergency Medicine staff teaching *'Forensic Medicine in the Emergency Department'*, '*Statements, Reports and Going to Court'* (annually)

GCUH Intern Orientation, '*Coronial Issues for Interns'* and *'Forensic Medicine for Hospital Doctors'* (annually)

Nurses in Watch-houses program, Southport and Beenleigh domiciliary, agency and emergency department nurses in-service training (2004-2016)

QPS Watch house Police Officers, Southport and Beenleigh Watch houses; in-service training (2004-2016)

Western Australia (1996 – 2003)

Clinical lecturer UWA Medical School in principles of medical care and forensic assessment of sexual assault victims (1995-2004) and general principles of clinical

forensic medicine (2000-2004), to the following groups:

- Fifth year medical students, University of Western Australia (UWA): groups of 20 students for 3 hr workshops 5 times yearly, supervision of students on 2 week optional attachments to SARC
- RACGP Family Medicine Program trainees (basic and advanced level), WA
- Resident Medical Officers in Gynaecology, King Edward Memorial Hospital for Women, Perth, WA.
- Rural General Practitioners as part of continuing medical education provided by Rural Divisions of General Practice and WA Centre for Rural and Remote Medicine.
- College of Emergency Medicine trainees, QEII Medical Centre, Perth, WA
- Assistance with developing and providing resources for PBL cases for medical students, UWA

Teaching to other professional bodies in WA in clinical forensic medicine and sexual assault medicine:

- Police - recruits, uniformed officers and detectives (WA Police Service)
- Lawyers - Dept of Public Prosecutions Court Vacation Conferences and Postgraduate Education Program (WA DPP)
- Judiciary - Annual W.A. District Court Judges' Conference
- Forensic Science Diploma/Masters Course, University of WA
- Emergency Nurses Association Continuing Education Program, WA
- King Edward Memorial Hospital Midwives Continuing Education Program
- Prison Health Services Postgraduate Education Program, WA
- Rural Health Care Professionals – nurses, health workers, social workers, psychologists, WA
- Sexual Health Clinicians – WA Postgraduate Education Program

SURFERS PARADISE Qld 4217

Email: [redacted]
:

Dear Mr Wilkins

Transfer of South-East Region Clinical Forensic Medicine Unit (CFMU) to Gold Coast Hospital and Health Service (HHS).

Health Support Queensland (HSQ) has recently completed an organisational change that will result in the transfer the forensic medicine services undertaken in the South-East Region (the area from the South Logan River to the New South Wales border) to the Gold Coast Hospital and Health Service.

The transfer of service responsibilities will occur on Monday, 1 October 2018. All enquiries related to the provision of forensic medical services in the South-East Region after this date should to be directed to:

Dr Cathy Lincoln
Deputy Director
Clinical Forensic Medicine Unit South East Region
Phone: [redacted]
Email: [redacted]

Dr Lincoln will be in contact with you shortly and will discuss communication processes and rostering arrangement commencing on October 1, 2018.

I am confident these new arrangements will ensure the continued provision of forensic medical services in the Gold Coast and Logan region.

Yours sincerely

Ms Ainslie Kirkegaard
Coronial Registrar
Coroners Court of Queensland
GPO Box 1649
BRISBANE Qld 4001

Email: [redacted]

Dear Ms Kirkegaard

Transfer of South-East Region Clinical Forensic Medicine Unit (CFMU) to Gold Coast Hospital and Health Service (HHS).

Health Support Queensland (HSQ) has recently completed an organisational change that will result in the transfer the forensic medicine services undertaken in the South-East Region (the area from the South Logan River to the New South Wales border) to the Gold Coast Hospital and Health Service.

The transfer of service responsibilities will occur on Monday, 1 October 2018. Enquiries related to the provision of forensic medical services in the South-East Region after this date should to be directed to:

Dr Cathy Lincoln
Deputy Director
Clinical Forensic Medicine Unit South East Region
Phone: [redacted]
Email: [redacted].

Please note that arrangements for the provision of forensic medical advice in relation to a healthcare related death (Form 1A) will continue to be managed through the Brisbane office of the CFMU. There is no change to these processes which reflects the preferences of your office.

I am confident the revised arrangements will ensure the continued provision of forensic medical services in the Gold Coast and Logan region.

Yours sincerely

STATEMENT OF CATHERINE ANN LINCOLN

I, Catherine Ann Lincoln, **Forensic Physician and Deputy Director, Forensic Medicine, Emergency Department, Gold Coast University Hospital,** of 1 Hospital Blvd, Southport, Queensland 4215, do solemnly and sincerely declare that:

Qualifications and experience

Question 2 - List your tertiary qualifications, the year you obtained them, and the institute from which the qualifications were obtained.

1. I qualified with a Bachelor of Medicine and Bachelor of Surgery from the University of Western Australia in 1987.
2. I have a Master of Forensic Medicine degree from Monash University (2002) and a PhD in Forensic Medicine from the University of Western Australia (2013).
3. I am a Foundation Fellow of the Faculty of Clinical Forensic Medicine (Royal College of Pathologists Australasia) and the Faculty of Forensic and Legal Medicine (Royal College of Physicians, United Kingdom).
4. I am an Associate Fellow of the Royal Australasian College of Medical Administrators (AFRACMA).

Question 3 -Detail your work history since you graduated from university.

5. I worked as an intern and resident medical officer in public teaching hospitals in Western Australia (Perth, Port Hedland and Kalgoorlie) between 1987 and 1990 (emergency medicine, orthopaedics, general medicine, general surgery, sexual health, psychiatry).
6. I worked as a senior house officer in public and private hospitals in the United Kingdom between 1990 and 1993 (general medicine, general surgery).
7. I worked as a full time general practitioner in Kimbolton, Cambridgeshire for 12 months in 1992-1993.

[redacted]

8. I worked as a part time general practitioner with a primary focus in women's health and as a sexual health clinic medical officer in Perth, Western Australia from 1993 to 2002.
9. I directed the Sexual Assault Medical Forensic Service in Western Australia from 1994 to 2003, employed full time by the Sexual Assault Resource Centre (SARC), King Edward Memorial Hospital for Women, West Australian Department of Health.
10. I was employed full time by Queensland Health as the sole forensic physician for the Gold Coast from 2004-2006, also providing forensic services to Logan.
11. I was Deputy Director, Clinical Forensic Medicine Unit (CFMU), South East Region (Gold Coast and Logan) from 2005 to 2018, employed full time by Queensland Health.
12. I have been employed full time by the Gold Coast Hospital and Health Service as Forensic Physician and Director, Forensic Medicine, Emergency Department since October, 2018.
13. In the course of my work, I have personally examined over 1000 patients alleging recent sexual assault and over 3000 consensually sexually active female patients.
14. The subject of my PhD thesis was *"Macroscopically detected female genital injury after consensual and non-consensual vaginal penetration: a prospective comparison study"*.

Question 4 - Identify any appointments to any boards and/or committees

15. I was appointed as the inaugural Chief Examiner for the Royal College of Pathologists Australasia (RCPA) Fellowship in Clinical Forensic Medicine (FFCFM) training program in 2015. From 2015-2021, I lead a team of CFM specialists at the RCPA in the development of a detailed and innovative fellowship training curriculum. In 2021, I oversaw the first formal examination in CFM, leading to the inaugural award of FFCFM (RCPA) by examination.
16. I am a member of the RCPA Faculty of Clinical Forensic Medicine (FCFM) Committee and sit on the RCPA Board of Education and Assessment (BEA).
17. I sit on the Editorial Board for the Elsevier Journal of Forensic and Legal Medicine.

18. I am a member of the Queensland Health Sexual Assault Interagency Guideline Working Group.
19. I am a member of the GCUH Watch house Emergency Nurse (WHEN) research committee.

Question 5 - Attach a current curriculum vitae

20. See ***Exhibit CL-01 - Curriculum vitae Catherine Lincoln***.

Current unit's functions and processes

Question 6 - Identify the name of the unit you currently work in as part of the Gold Coast Hospital and Health Service. What are the roles and functions of your unit? Who do you report to?

21. I work as Director of the Forensic Medicine service which is structurally part of the Emergency Department at the Gold Coast Hospital and Health Service (GCHHS).
22. I report to Dr David Green, Director of Emergency Department.
23. The GCHHS Forensic Medicine service is responsible for provision of forensic services to Gold Coast and Logan Police Districts, and Gold Coast University Hospital, Robina Hospital Logan Hospital involving those aged 14 years and over. In summary, the service;
    a) Provides forensic examinations for the Gold Coast and Logan areas at three hospitals (GCUH, Robina Hospital and Logan Hospital).
    b) Has responsibility for healthcare provision to Southport and Logan District Watch houses.
    c) Provides medicolegal reports at the request of police and Office of the Director of Public Prosecutions (ODPP) in relation to clinical forensic examinations and clinical forensic matters not involving examination (eg review of material, toxicology, etc).
    d) Assists the South Eastern Coroner with review of clinical matters relating to death (within scope).

Question 7 - Identify the duties/responsibilities of your position.

24. As Director of Forensic Medicine, I:

a) Have responsibility for provision of clinical forensic medicine services to police, courts and the coroner (excluding Form 1A and Cause of Death advice) in Gold Coast and Logan Police Districts.

b) Provide leadership of clinical forensic medical services in Gold Coast and Logan Police Districts, and at Gold Coast, Robina and Logan Hospitals.

c) Comply with the provisions of appropriate legislative and regulatory policies as they relate to clinical forensic medical services.

d) Supervise nine (2.375fte contracted and 2 casual) forensic physicians and two (1.6fte) administration officers and clinical oversight of up to 10 watch house emergency nurses (WHENs).

e) Provide impartial medico-legal advice and reports to police, ODPP, government agencies and departments.

f) Have responsibility for the GCHHS Forensic Medicine department budget.

g) Participate in teaching and research activities that directly support defined clinical objectives.

h) Support education and training programs at both undergraduate and postgraduate levels.

i) Recruit and train doctors working in the department.

25. As a forensic physician providing frontline services, I am responsible for:

a) Provision of timely, efficient and competent clinical forensic medical services.

b) Participation in 24 hour 7 day forensic roster.

c) Maintenance of current best practice, knowledge and clinical expertise, of medical and forensic practice.

[redacted]

d) Maintenance of knowledge and qualifications required as an expert witness, across the full spectrum of clinical forensic medical practice

Question 8 - Identify how many staff you are responsible for, and outline their roles (eg physicians, nurses, administrative staff etc)

26. In my current role, I have responsibility for the following staff;
    a) Nine (2.375fte contracted; 2 casual) forensic physicians.
    b) Two (1.6fte) administration officers.
    c) Clinical supervision of up to 10 watch house emergency nurses (WHENs) employed by the GCUH Emergency Department and working at Southport and Logan District police watch houses.

Question 9 - When was the unit you currently work in created? Is it supervised by the state-wide Clinical Forensic Medicine Unit (CFMU); and if not, when did it detach from the CFMU (if it ever did)? Explain the reasons for, and the background to, your unit detaching from the CFMU.

27. The Gold Coast Hospital and Health Service (GCHHS) Forensic Medicine service was established in October, 2018 after the separation of the Gold Coast/Logan Clinical Forensic Medicine Unit (CFMU) from the Brisbane CFMU.
28. The separation resulted from concerns raised about the provision of forensic services to the Gold Coast community under a centralised model for the provision of clinical forensic services was instigated in Queensland. If required, further information in relation to this could be sought from Dr David Green, Director of Emergency Department, GCHHS and Dr David Spain, Emergency Physician and Deputy Director of Emergency Department, GCHHS at the time.
29. The GCHHS Forensic Medicine service is structurally part of the Emergency Department.

30. The state-wide CFMU does not supervise the GCHHS Forensic Medicine service; relevant state-wide policies and standards issued by the Director CFMU are applied within the jurisdictional requirements of the HHS.

See ***Exhibits***

CL-02 Letter AC SER QPS (Sept 2018)

CL-03 Letter Coroner SER (Sept 2018)

CL-04 Letter Coronial Registrar (Sept 2018)

CL-05 Letter DPP (Sept 2018)

CL-06 Letter GC QPS (Sept 2018)

CL-07 Letter MSHHS (Sept 2018)

CL-08 Letter QPS (Sept 2018)

CL-09 Letter State Coroner (Sept 2018)

Question 10 - Who administers sexual assault investigation kits (SAIKs) at your unit? Do nurses administer SAIKs? Does your unit also administer just-in-case kits? If so, is there any difference in who administers just-in-case kits?

31. All sexual assault forensic examinations whether at the request of police (using Sexual Assault Investigation Kits or SAIKs) or without police involvement (so-called 'Just in Case' kits or JIC kits) are performed by forensic physicians. Our service does not currently employ nurses.

Question 11 - Detail the training that practitioners undertake in order to be able to administer SAIKs. Have you designed the training process? How was it designed and to what training standards does it seek to apply with (if any)? Identify and attach your unit's training guides, manuals and policies (including any entrustment forms).

32. I developed the GCUH workplace-based skills training program to prepare doctors to conduct sexual assault forensic examinations (including use of SAIKs and JICKs) to align with the entrustment process required for the Faculty of Clinical Forensic Medicine Fellowship training program curriculum and the credentialling requirements

for Gold Coast Hospital and Health Service Senior Medical Officers (Forensic Medicine). This training combines simulated mannequin and real patient examinations and can take between three and six months to achieve 'entrustment level 4' depending on level of roster participation.

See ***Exhibits:***

CL-10 RCPA Faculty of Clinical Forensic Medicine Trainee Handbook 2022

CL-11 RCPA Position Statement Role of the Specialist in Clinical Forensic Medicine

CL-12 GCUH new SMO forensic induction record

CL-13 GCUH supervision entrustment hierarchy

CL-14 GCUH forensic examination entrustment form

CL-15 GCUH medicolegal report log template.

33. A range of resources and reading material to complement the skills-based training is provided to all new SMOs including RCPA Faculty of Clinical Forensic Medicine standards and UK Faculty of Forensic and Legal Medicine recommendations and guidelines (already provided in response to Notice 2022/00107).

34. Requirements for employment with the service include enrolment in the Monash University Master of Forensic Medicine degree. Attendance at state and national sexual assault workshops, seminars and conferences is encouraged and supported by GCHHS.

35. In 2019, the RCPA sought clarification from Queensland Health in relation to training standards and requirements for sexual assault examinations.

See ***Exhibit CL-16 Correspondence between RCPA and Qld Health re sexual assault training 2019***

Question 12 - Broadly, what skills and experience are necessary to correctly conduct a forensic medical examination?

36. A clinician undertaking sexual assault forensic examination requires:

    a) Good communication and interpersonal skills.

b) Broad general medical experience ideally including emergency medicine, primary care, gynaecology, psychiatry, addiction medicine and sexual health care.

c) Sound knowledge of pathophysiology of disease and trauma.

d) Sound knowledge of genito-anal anatomy (surface and internal).

e) Experience in examination of 'normal' female genitalia (external and internal) preferably gained in primary care, emergency medicine, gynaecology, sexual health, obstetrics where patients have not been recently traumatised.

f) Experience in examination of 'normal' ano-rectum preferably gained in primary care, emergency medicine, sexual health, surgery where patients have not been recently traumatised.

g) Competence in clinical reasoning and a methodical and analytical approach to the interpretation of findings.

h) Ability to work effectively within a multidisciplinary team (police, social workers, other health care professionals).

Question 13 - How do complainants/victims come into contact with your unit? Do they approach your unit directly, or do police bring complainants to your service?

37. Sexual assault patients/complainants come into contact with the GCHHS forensic service after reporting an incident to police or after presenting to one of the three emergency departments covered by the service (GCUH, Robina or Logan Hospitals).

a) If a patient/complainant makes a report to police, police contact the duty forensic physician who notifies the emergency department social worker and triage nurse of imminent arrival.

b) If a patient/complainant presents to an emergency department without having spoken to police, an ED social worker discusses options for healthcare and forensic examination (SAIK or JICK) and contacts duty forensic physician accordingly.

CL-18 GCHHS Sexual Assault Forensic Examination Pathway Consent_GC10823

CL-19 GCHHS 'Just in case' forensic examination patient information brochure

Sexual assault investigation kits (SAIKs)

Question 14 - Explain your experience in using and/or designing SAIKs in Western Australia and Queensland prior to 2018.

Western Australia 1994-2003

38. I commenced working as a part time medical officer at the Sexual Assault Resource Centre (SARC), Western Australia Department of Health in 1994. Part of my role was to provide sexual assault forensic examinations.

39. In 1995, I became Director of the SARC Sexual Assault Medical Forensic Service, a position I held until 2003. During this time, I developed female and male forensic examination kits (SAEK), an early examination kit (EEK) and a comprehensive manual outlining details of forensic and medical care of patients who reported sexual assault. I sought information from other States and collaborated with PathWest Forensic Biology scientists to ensure the kits met the needs of both clinicians and laboratory staff.

40. The WA SARC kits were put together by SARC staff and included swabs, slides, yellow top containers, gauze wipes, sticker labels and a 25 page medical record which included pages to record details of the incident and relevant information, body diagrams and sample list.

41. The WA SARC kits were used state wide. They were distributed to regional hospitals around the state for use by hospital doctors together with a sexual assault examination equipment box containing necessary items to perform forensic examinations (eg speculum, anoscope, stationery, camera) for use in conjunction with the kits. SARC

doctors also used the equipment boxes when required to examine patients at other hospital sites in the metropolitan area.

42. At this time, the WA PathWest Forensic Biology laboratory provided written feedback to clinicians re quality of samples collected in each sexual assault examination kit.

See ***Exhibit CL-20 SARC WA forensic sample list and analysis clinician feedback form (2002)***

43. Recent personal communication with Dr Kym Farrington, current SARC WA Medical Forensic Head of Department confirmed that the sexual assault kits used by SARC forensic clinicians are now produced by Sanax Medical (ISO standard 18385 approved). The kits are not dissimilar to those developed when I worked there in 2003, however are now unisex and categorised as small, medium and large to cater for different time since incident (TSI) scenarios. Toxicology kits are separate items.
See ***Exhibits***
CL-21 SARC WA sexual assault kit contents (2022)
CL-22 Sanax Medical - ISO 18385 Certificate (2019)

44. During this time, I was invited by the National Institute of Forensic Science (NIFS) to provide information in relation to clinical forensic sexual assault kits to national Special Advisory Groups (or SAGs).

Queensland 2004-2018

45. I commenced work as a Forensic Medical Officer on the Gold Coast, Queensland in January 2004. I was employed by Queensland Health Clinical Forensic Medicine Unit (CFMU) and based in an office at Surfers Paradise Police Centre, Ferny Ave, Surfers Paradise. Part of my role was to provide sexual assault forensic examinations at the request of police; I examined patients at Gold Coast University Hospital and Logan Hospital using the Sexual Assault Investigation Kits (SAIKs) in use in Queensland at that time.

See ***Exhibits***

CL-23 Qld Sexual offences medical protocol booklet (2004)

CL-24 Photograph Qld SAIK (circa 2006)

46. In 2006, I was asked by Dr Robert Hoskins, Director, CFMU at the time, to suggest any appropriate improvements to the Queensland SAIK and to participate as co-lead in a collaborative SAIK improvement project with Forensic Biology staff at the John Tonge Centre, Queensland Health Scientific Services.

47. I drafted a revised SAIK booklet to address challenges for regional doctors required to perform forensic examinations infrequently with limited training. My suggested booklet changes were not taken up and my recollection is that the SAIK Improvement project was not completed because of laboratory staff changes.

See ***Exhibits***

CL-25 Draft QHSS proposal SAIK improvement project (2006)

CL-26 Draft revised SAIK protocol booklet by CL – not taken up (2006)

CL-27 Email CL to QHSS re SAEK revision (2007)

48. In the early years of my employment as an FMO in Queensland (around 2004-2007), I tried to engage with Forensic Biology staff at Queensland Forensic and Scientific Services (QHFSS) in relation to Early Evidence Kits (EEKs) which I had developed for use in Western Australia and found to be useful to preservation of evidence in regional areas while a person was awaiting transfer to hospital. I felt Queensland might benefit similarly. However, this idea was not taken up. EEKs are now in routine use in a number of Australian states.

49. During the same time period, I endeavoured to interest Forensic Biology staff in adding other samples I had found to be of value in WA, to the Queensland SAIK, namely first void urine, gauze wipe genitalia, oral rinse and inner thigh swabs. Because forensic clinicians at SARC in WA routinely received notification of the analysis results for samples taken in forensic examinations, I was aware that these samples had the potential to detect semen/sperm, and I was keen to improve evidence collection in

Queensland in the same way. These suggestions were not taken up. I recall being told by Forensic Biology staff that QHFSS did not have a centrifuge, a piece of equipment required to 'spin down' fluid such as urine of saliva/water to concentrate cells such as sperm. When I explored the possibility of purchasing a centrifuge, I found that centrifuges were relatively inexpensive however I was unable to generate any interest from the laboratory or Director CFMU at that time in purchasing one.

50. I designed a sexual assault toxicology form to accompany blood and/or urine specimens for toxicological analysis which was included in the SAIKs in 2011.

See ***Exhibits***
CL-28 FSS CFMU Sexual Assault Toxicology form (2011)
CL-29 Sexual Assault Toxicology form (2017)

51. I have used the Queensland SAIKs for all sexual assault forensic examinations that I have done at the request of police since employed as a Forensic Medical Officer by the CFMU and Forensic Physician by the Gold Coast Hospital and Health Service (2004 – present).

52. I was not directly involved in any SAIK design or consultation process after 2006 but have provided feedback to Director, CFMU in relation to various changes to the SAIKs since that time.

Question 15 - List the contents of the current SAIK.

53. The current SAIK contains:
    a) Six (6) unlabelled wooden swabs
    b) One paper drop sheet in clip-seal plastic bag
    c) One 3 page FSS 'Medical examination information form – DNA' and one 1 page 'Sexual assault toxicology' form; placed in a clip-seal plastic bag.

These items are provided in an open clear tamper proof bag to be used for sealing exhibits into, at completion of forensic examination.

See ***Exhibits***

CL-30 FSS Medical examination form – DNA (2022)

CL-31 Photograph of SAIK contents (2022)

54. Toxicology kits used for sexual assault are the same as those used for traffic offences; one for urine and one for blood. They are separate to the SAIK.

See ***Exhibits***

CL-32 Photograph (1) of Forensic Toxicology kit (2022)

CL-33 Photograph (2) of Forensic Toxicology kit (2022)

55. Individual clothing items are placed into brown paper bags and labelled/sealed. Police may provide these bags at the time of examination but the service also purchases them to have a ready supply.

Question 16 - How long have you been working with Queensland SAIKs? Has the SAIK model changed during that time? If so, provide details.

Question 17 - Have any of the changes to the SAIK model improved or worsened the SAIK model? If yes, explain how and when the change was.

Question 18 - In relation to any change that saw the removal of diagrams/space for diagrams on the booklet provided with the SAIK, what is your view of that change? What communication, if any, did you have with Dr Adam Griffin concerning such changes?

****Please note that I have addressed Questions 16, 17 and 18 in paragraphs 56-100***

56. I have used the Qld SAIKs for all sexual assault forensic examinations done at the request of police since employed as a Forensic Medical Officer by the CFMU and Forensic Physician by the Gold Coast Hospital and Health Service (2004 – present).

57. It is difficult to be accurate about the timing of some of the SAIK changes because we did not receive formal notification of all changes, and supplies of older kits were still being utilised by police for some time before they were supplied with updated versions.

58. I understand the following changes to have occurred during the period 2004-2022:

Cessation of clinician-made slides at time of swab collection

59. Between 2007 and 2009, there were discussions between Forensic Biology and CFMU about the possibility of ceasing the making of slides by examining clinicians at the time of swab collection (that is, smearing a glass slide with a swab containing adherent biological material) and for slides to be made in the laboratory by scientists at a later time from the swab.

60. The making of slides by clinician at the time of examination was routine practice in other States and the process I was familiar with in WA. The reason given by the laboratory for the proposal to cease the making of slides by clinicians was the poor standard of smears collected by some clinicians doing these examinations and a desire to achieve more consistent smear collection (certain thickness, area smeared, etc).

61. As a non-scientist but having completed a Master of Forensic Medicine degree at Monash University in 2002 which included a module covering some basic principles of forensic science (Elements of Forensic Science), my understanding of forensic biology processes with respect to forensic samples collected after sexual assault, was that two swabs should be taken from each site, the first used to make a smear on a slide to be examined microscopically for sperm and potentially used to test for acid phosphatase (AP) and/or prostatic specific antigen (PSA) and the second retained for DNA extraction if indicated.

62. While the cessation of slide-making at time of swab collection was attractive to clinicians because of the additional steps required to label glass slides and create the smears, I had concerns about the potential loss of evidence given the smears would likely be made from a dried swab at some time after the initial examination and I could find no published data to reassure me that evidence collection would not be compromised. I sought advice from a number of other State laboratories who indicated that they did not consider this to be appropriate and said they would advise against it.

63. I suggested a simple comparison study to determine whether making slides in the laboratory after a delayed period of time rather than by the clinician at the time of swab

collection, would have any effect on the likelihood of detection of sperm/DNA. This suggestion was not taken up.

See ***Exhibit CL-34 Proposed sperm microscopy project by CL – not taken up (2009)***

64. I sought clarification in 2009 from Forensic Biology scientists via the CFMU Director at the time, that evidence would not be compromised by the cessation of slide-making by clinicians and was told in an email that swabs would be tested for DNA if any doubt about the slide. One disadvantage outlined by the scientists was that if a swab was mouldy, creation of a slide in the laboratory would not be possible indicating that storage issues and delays in kit transfer to the laboratory had the potential to affect the outcome of sample analysis.

See ***Exhibit CL-35 Emails CFMU and QHSS cessation of making slides at time of collection***

65. Slide-making by clinicians at time of swab collection was subsequently ceased and slides were no longer included in the SAIKs. In 2011, I sought clarification about the analysis processes used by Forensic Biology in 2011 about which I made a note for my own understanding.

See ***Exhibit CL-36 SAIK swab laboratory procedure post slide cessation (2011)***

66. I acknowledge that laboratories in different jurisdictions use different processes to analyse sexual assault forensic examination kits and that there is variation in relation to tests carried out on kit samples (eg reporting time since intercourse estimates). However, I believe that poor quality slide creation is a training issue and could have been addressed with appropriate education and instructive resources.

67. I understand from discussion with Dr Maria Nittis, Head of Department, Clinical Forensic Medicine at the Victorian Institute of Forensic Medicine (VIFM) that the Hazpak SAIK currently in use in Victoria, contains slides with a clearly marked area indicating where the examining clinician should make the smear from the swab, to some extent mitigating inconsistency of material deposited.

68. Dr Nittis published a peer-reviewed article in 2021 in relation to research carried out collaboratively between clinicians and laboratory staff in NSW, exploring the necessity for slides in SAIKs.

See ***Exhibit CL-37 Nittis et al. Preparing semen slides in sexual assault – do they who smear first smear best? J For Leg Med 79 (2021) 102130***

Other SAIK changes

69. In 2012, changes were made to the SAIKs which were explained in a letter to Forensic Medical Officers (FMOs) from Dr Adam Griffin, Director CFMU at the time. I was not involved in this process. The key changes appeared to be that the requirement to collect reference DNA samples from a victim/complainant was removed (removal of EDTA blood tubes from kits) and that the medical record booklet was to be phased out and replaced with a three page form to record only information of value for the laboratory.

a) In Jan 2014, I sought clarification from Cathie Allen who was at that time Managing Scientist Forensic DNA Analysis and Forensic Chemistry, FSS, about new SAIKs after a query from Dr Sally Jacobs, one of my staff. Dr Jacobs had received a query from Bundaberg in relation to new SAIKs and had been forwarded an email thread showing that Ms Allen had informed Dr Griffin, then state wide Director CFMU re SAIK changes in July, 2013 with attached images of the new SAIKs. This information, it appeared, had not been shared with Gold Coast forensic clinicians. Ms Allen summarised the changes in her email response to my query (January 2014) and attached photographs of the new kits.

b) Because police throughout the state (including Gold Coast and Logan) seemed to have variable supplies of different versions of the SAIKs, and as a result of poor communication to clinicians about the SAIK changes, we did not have accurate information about which kits were the most recently updated and should be in use. There did not appear to be support for de-commissioning old versions of SAIKs in order to use newer versions, possibly due to financial considerations.

c) As the Gold Coast forensic service was part of the Queensland Health FSS CFMU with four full time forensic medical officers employed by Qld Health at that time, and because we periodically responded to calls for advice from around the state in relation forensic services, I felt that we should have been kept informed of the SAIK changes. I was Deputy Director, CFMU SER at that time with responsibility for clinical forensic service provision to Gold Coast and Logan police districts at that time.

CL-38d Email attachment to CL-38a Sexual Assault Investigation Form DNA (2014)

CL-38e Email attachment to CL-38a Sexual Assault Toxicology Form (2014)

CL-39 Draft SAIK form (2012)

Removal of medical record booklet from SAIK

70. Around 2012, I became aware from discussions with forensic colleagues that there was much debate about who should be financially responsible for Qld SAIKs and that the medical record booklets were considered an expensive component. This was around the time of proposed SAIK changes explained to us in a letter from Dr Adam Griffin mentioned above.

71. At that time, I raised concerns with Dr Griffin about removing the medical record booklet from the SAIK and the potential for examiners to disregard the value of injury documentation without a series of body diagrams to use and the implications for regional clinicians required to do sexual assault forensic examinations infrequently. He told me that examining clinicians could access their own diagrams and add them to

their files if they so wished. He did not appear concerned that forensic examinations by clinicians unfamiliar with the necessary process, might be compromised.

72. I also raised concerns with Dr Griffin that without readily available carbon copy booklets as previously, police would not receive a copy of the examination findings at the time of the examination for inclusion in the evidentiary brief. He replied that clinicians could photocopy diagrams and give to police if they so wished. I have done this with my own cases in an effort to ensure investigators have the necessary information immediately, however it is an additional onerous task for clinicians at the end of a lengthy process and is not done in most instances because of time constraints.

73. Proposals at that time to include unique identifier 'bar code' stickers in the SAIKs to affix to swabs and samples were not progressed though I have seen them used in other evidence kits by Scene of Crime Police Officers. I believe these would have enhanced SAIK evidence collection quality.

74. Since about 2014, SAIKs have not contained a medical record with diagrams. We utilised our own sourced diagrams and stored these in forensic files.

See ***Exhibit CL-40 Photograph Qld SAIK (2014)***

75. In August 2017, Dr Griffin disseminated a sexual assault examination medical protocol and record to all CFMU staff (Document number 34442V1). This was not included in the SAIKs and I'm not aware if it was also disseminated to others around the State who might be required to perform sexual assault forensic examinations.

See ***Exhibit CL-41 Sexual offences medical protocol - not included in SAIK (2017)***

76. While the diagrams and instructions in this medical protocol and record are of value, there is confusing reference to the use of unique identifier bar code stickers which have never eventuated, and to the taking of DNA reference samples using a separate kit which is not provided with the SAIK by police. Examiners are required to photocopy the SAIK laboratory form for their own reference when writing the examination report and if police request information about injuries, the diagrams must be photocopied.

77. In summary, the design of the Queensland SAIK and necessary documentation is not user-friendly for examiners thus creating the potential to compromise evidence collection.

78. In my view, the format and contents of the recently updated Victorian Institute of Forensic Medicine (VIFM) SAIK-equivalent proforma document is ideal for recording details of sexual assault forensic examinations.

See ***Exhibit CL-42 VIFM sexual assault proforma (16 June 2022)***

Removal of reference DNA sampling items

79. I understand that around that time, reference DNA sampling had changed from blood (EDTA tube) to saliva sampling (sponge-type swabs) and was to be done using a separate newly designed kit which was not to be included in the SAIK.

80. Since this time, I understand that police have collected reference DNA samples from complainants and offenders.

81. I have never received a supply of these kits from FSS or police or been given training in how to use them.

82. Removal of the reference DNA sampling aspect from the SAIKs reduced the duration of clinician time needed to conduct the forensic examination.

83. The issue of reference DNA samples has recently been re-visited during review of the Qld Sexual Assault Interagency Guidelines by the Interagency Guidelines Working Group lead by the Department of Justice and Attorney General. I was recently invited to join this working group and attended my first meeting on 28 July 2022. I did not receive a copy of minutes of this meeting but recorded my own notes at the time.

See ***Exhibits***

CL-43 Emails with FSS re proposed edit to SA interagency guidelines re reference DNA samples

CL-43a Qld SA Interagency guidelines - under review (July 2022)

CL-105 Handwritten notes made by CL during Queensland Government Interagency Sexual Assault Response Guidelines working group meeting 28 July 2022

84. I believe reference DNA samples could reasonably be collected by clinicians. However, because the clinician would need to obtain informed consent from the sexual assault patient/complainant before doing so, they would require information and assurances in relation to processing of the sample, how long it would be kept for, where it would be stored, and whether there is potential for it to be included in the criminal DNA database.

Removal of fingernail clippings/scrapings bags

85. The SAIKs available in 2004 contained small clip-seal bags labelled 'fingernail scrapings/clippings'. My recollection is that clinicians used either toothpicks to collect material from under the nails or nail scissors to cut nails for later examination in the laboratory. The scrapings or clippings were placed into the bags provided but neither toothpicks or scissors were provided in the kits so had to sourced by clinicians.

86. Around 2006, I attended an international forensic conference and brought back a wedge-shaped swab designed to optimise retrieval of material from under fingernails. I gave the swab to the Director, CFMU at the time and suggested we discuss the possibility of including in the SAIKs with Forensic Biology. This idea was not taken up.

87. Around 2010, I was informed by a Gold Coast Scenes of Crime Officer (SOCO) that police were using specially designed fingernail kits to retrieve material from under fingernails. I was unable to obtain these kits from FSS or police for use in sexual assault forensic examinations.

See ***Exhibit CL-44 Photograph of QPS SOCO Gold Coast fingernail kit (2010)***

88. The current SAIKs do not contain any receptacle or equipment to collect fingernail scrapings or clippings; these can be important in corroborating a struggle between victim and perpetrator or merely establishing contact with a perpetrator.

89. My current practice is to request that police organise collection by a SOCO using the specifically designed fingernail kit, however I am uncertain whether or not this occurs.

90. I believe that inclusion within the SAIK of equipment to collect material from under fingernails or fingernail clippings or provision of a fingernail kit together with the SAIK would be preferable to ensure all possible evidence can be collected by the clinician at the time of examination.

Changes to swabs in SAIKs (number, loss of labelling)

91. At some time in the last 10 years, possibly following the cessation of slide-making by clinicians and removal of slides from the kits, the number of swabs provided in a SAIK was reduced to six (6).

a) My recollection of using the SAIKs prior to this change, was that there was an additional label was affixed to the swab overlying the manufacturer's identification swab label; these additional labels identified swab sites and provided space for the examiner to record identifying details such as date and time of collection, and name of examiner. Each swab was clearly identified by site; in particular, denoting individual male or female genital sites.

b) No single forensic examination ever required the use of all swabs provided because some were designated to be taken from male genital sites and some female genital sites. In addition, because not all cases involved allegations of penetration of three orifices (oral, vaginal, anal) or the need for skin swabs or swabs to detect saliva from bites/licking, there were usually 'spare' swabs within each SAIK that could be utilised and re-labelled as having been taken from a different site. I recall doing this fairly frequently; using a thick black marker to obscure the pre-typed 'site' and re-labeling with the site the swab was actually collected from.

c) Extrapolating from the forensic sample lists on page 19 (female) and page 22 (male) of the Qld Sexual offences medical protocol booklet (2004) **[see Exhibit CL-23],** I would estimate that there were probably 10-15 swabs provided in each SAIK prior to the change which reduced the SAIK total swab number to six.

92. Six swabs is not enough to take even one swab from all relevant sites in certain cases, let alone two swabs from each site as is recommended in other jurisdictions. For example, an allegation of oral, vaginal, anal penetration with a penis requires sampling

from mouth, inner labia, low vagina, high vagina, peri-anal skin, anus, rectum +/- endocervix.

93. Recommendations in 2010 Vincent Report of the Inquiry into the Circumstances that led to the Conviction of Farah Abdulkadir Jama included:

a) the taking of additional control swab/s from the examination trolley surface to provide an opportunity to confirm that the working surface upon which equipment is set up, was free from DNA should there be a subsequent concern re contamination (see item 8; Attachment B, page 74).

b) Each kit to contain sufficient swabs to cater for most examinations so that extra kits will need to be 'broken into' for more swabs only rarely (see item 13; Attachment B, page 75)

c) Swabs should have polyester tips and plastic or metal stems. Current Qld SAIK swabs are cotton tipped with wooden stems. Cotton does not yield DNA as readily as synthetic fibre and wood apparently inhibits the PCR reaction.

See ***Exhibit CL-45 Vincent FHR. Inquiry into the circumstances that led to the conviction of Mr Farah Abdulkadir Jama. Victorian Department of Justice, 2010*** Available from:
https://assets.justice.vic.gov.au/.../vincentreportfinal16may2010.pdf

94. In my experience, swabs with wooden stems are more likely to break during sample collection which creates clinical risk when used to sample internal sites such as the vagina or anus.

95. Within the last 10 years, the labels previously affixed to swabs in the kits to denote sites required for sampling (e.g. 'low vaginal', 'high vaginal' etc) were removed; the swabs now provided in the SAIK are not distinguishable. This change may have been in preparation for the planned introduction of unique identifier bar code stickers which did not eventuate. This means that when setting up for an examination, clinicians are required to identify swabs themselves to prevent mix-up of swabs on the trolley while examining the patient and reaching for swabs while holding a speculum or anoscope in

position with the other hand. It also provides challenges for clinicians who do these examinations infrequently and may need prompting as to relevant sites to sample.

Changes to SAIK bag containing necessary items, used for sealing collected evidence for transfer to laboratory

96. Around 2014, the SAIK bag containing the items required for collection of evidence during a sexual assault forensic examination changed from an A4-sized padded brown paper envelope to a clear A4-sized tamper evident security bag. Neither were sealed when provided to the clinician by police with contents readily able to fall out and the potential for external contamination.

97. To avoid contamination of contents, the Gold Coast and Logan forensic service has endeavoured for many years to source SAIKs in batches of at least 30 from QPS, to minimise handling and transport of individual kits by investigating police at the time of each examination.

98. Another recommendation of the 2010 *Vincent Report* was that all equipment should be certified DNA-free and drawn from a sealed single-use kit to reduce the opportunity for contamination. (see item 2, Attachment B, page 73).

    See ***Exhibit CL-45 Vincent FHR. Inquiry into the circumstances that led to the conviction of Mr Farah Abdulkadir Jama. Victorian Department of Justice, 2010***

99. I have personally come across two 'clean' swabs drawn from two separate SAIKs with hairs adherent to the under-surface of the manufacturer's swab label. There are a number of possible sources of such contamination including the swab manufacturer, the person who puts together the SAIKs or during transport and handling of the SAIK by police prior to examination.

    See ***Exhibits***

    CL-46 Photograph of 'clean' forensic swab (1) with adherent hair under label

    CL-47 Photograph of 'clean' forensic swab (2) with adherent hair under label

100. It is clear that the current SAIKs in Queensland are not fit for purpose and do not meet Australian Standard ISO 18385: 2017.

See ***Exhibit CL-48 AS ISO 18385-2017 Minimizing the risk of human DNA***

Question 19 - Identify any relevant forensic medicine guidelines or standards concerning how an intimate medical examination should be conducted and what items and consumables should be used in that examination. Advise if any of those guidelines are more widely accepted than others, or if they refer to evidence-based research.

101. While there are many good resources in the area of forensic medicine, the most valuable with respect to sexual assault medical examination and forensic sampling in my view are:

a) The Royal College of Pathologists Australasia (RCPA) Faculty of Clinical Forensic Medicine (FCFM) published guidelines:

See ***Exhibit CL-49 Royal College of Pathologists Australasia (RCPA) Faculty of Clinical Forensic Medicine (FCFM) list published guidelines (weblinks x 9)***

Guideline - Evidence Based Forensic Sampling Standards
Guideline - Assessment of Capacity to Consent to Examination and Forensic Procedures
Guideline - Cleaning/Decontamination of Forensic Examination Suites
Guideline - Clinical Forensic Assessment and Management of Non-Fatal Strangulation
Guideline - Compulsory and/or Intimate Body Examinations of Persons in Custody
Guideline - Medical Review of Clinical Forensic Medical Reports
Guideline - Photography for Clinical Forensic Medicine
Guideline - The Presence of Chaperones during Intimate Forensic Medical Examinations.
Guideline - Sexually Transmitted Infection Management in Patients Who Have Experienced Sexual Violence

See in particular ***Exhibit CL-49a Royal College of Pathologists Australasia (RCPA) Guideline - Evidence Based Forensic Sampling Standards***

b) The Royal College of Physicians (United Kingdom) Faculty of Forensic and Legal Medicine (FFLM) published recommendation/guidelines. I have already provided fifteen (15) relevant FFLM documents in response to Notice 2022/00107; I have re-attached seven (7) of particular note:

e) Vincent FHR. Inquiry into the circumstances that led to the conviction of Mr Farah Abdulkadir Jama. Victorian Department of Justice, 2010

See ***Exhibit CL-45 Vincent FHR. Inquiry into the circumstances that led to the conviction of Mr Farah Abdulkadir Jama. Victorian Department of Justice, 2010***

102. These texts and publications are evidence-based in so far as is possible in a field such as clinical forensic medicine where research is challenging for a multitude of reasons. I have personal experience of the difficulties faced by researchers in this field, having completed a PhD in forensic medicine at University of WA in 2013.

103. In most Australian jurisdictions, limited collaboration between laboratory scientists and forensic clinicians, together with the lack of scientific feedback to clinicians about analysis results and quality of the samples they collect, does not foster an environment for evidence-based decision-making in relation to SAIK development and improvement. However, due to efforts to achieve agreement with forensic scientists to provide formal forensic clinician feedback re SAIK analysis, some Australian states such as WA and NSW, have managed to conduct valuable research to inform future forensic practice.

Question 20 - Do the documents referred to in para 19 provide guidance as to what type of swabs and how many swabs (or similar devices) should be used in conducting a typical SAIK? If yes, what do those documents advise?

104. These documents and texts together provide valuable information to inform decisions in relation to sexual assault forensic examination, SAIK structure and content.

105. While SAIK development must involve laboratory scientists to ensure design meets analysis requirements, kit design by necessity is within the purview of the clinicians who collect evidence. Appropriate clinical proformas which prompt inexperienced examiners, bar-coded sticker labels and provision of all necessary items to collect any forensically relevant material to assist clinicians enhances evidence collection significantly. In my view, poor engagement with clinicians in development of SAIKs in Queensland has compromised the quality of forensic evidence collection.

106. Achievement of a nationally agreed standard SAIK is ideal. This can only happen with collaboration between a nationally recognised professional body for forensic clinicians such as the RCPA Faculty of Clinical Forensic Medicine (FCFM), state and territory forensic laboratories. Any such kit must be 'fit for purpose' for both clinicians and laboratories and meet relevant Australian Standards (ISO 9001; 2015 and 18385: 2017). See ***Exhibit CL-48 AS ISO 18385-2017 Minimizing the risk of human DNA contamination in products used to collect, store and analyze biological material for forensic purposes – Requirements***

a) I do not have a copy of ISO 9001; 2015 but understand it to relate generally to quality management systems for wider application across many workplaces.

b) I do not have direct knowledge of whether or not it is a necessary requirement for scientific laboratories to adhere to ISO 9001; 2015 but would think that most laboratories would endeavour to do so with respect to systems management. The following weblinks may assist with an understanding of the scope of this particular Standard.

ISO 9001:2015(en), Quality management systems — Requirements

107. It could be argued that involvement of state Offices of the Directors of Public Prosecution (ODPPs) and police in discussions about what should be contained with forensic evidence kits would add value. Correlation of evidence gathering processes with legal requirements for the prosecution of offences can only enhance the forensic value of evidence kits.

108. Some accredited forensic kit providers in Australia (eg Hazpak, Sanax) have for some years worked closely with forensic clinicians to design DNA-free kits which meet relevant Australian Standards (ISO-18385; 2017) and are 'fit for purpose'; purchase of these kits by various States and territories will assist in achieving some degree of national consistency.

[redacted]

Question 21 - How do you obtain or order the SAIKs used at your unit?

109. On occasion, police will bring a SAIK with them to the hospital when they bring a patient/complainant for examination; they may or may not bring other necessary items such as toxicology kits or paper bags to collect clothing items.

110. In the past, when we were not permitted by CFMU Director Dr Adam Griffin/FSS to keep supplies of SAIKs at hospital examination sites, there were delays for patients and extensive call-out periods for forensic clinicians because some investigating police did not know where kits were kept in their District or how to source them. Invariably, the most significant delays resulting from this situation were after hours.

111. Our service orders SAIKs and forensic toxicology kits from the Queensland Police Service. I understand that they are sourced centrally from QPS Child Abuse & Sexual Crime Group Admin [redacted].

   a) On the Gold Coast, kits are picked up from Southport Police Station and delivered to our office at GCUH by the hospital police liaison officer. Contact person for ordering kits is Di Smith, Administrative Supervisor, Southport Police Station. [redacted]

   b) In Logan, kits are ordered by our service from Logan Criminal Investigative Branch (CIB) and delivered to the Police Beat at Logan Hospital where the nurse responsible for oversight of the forensic examination room retrieves them.

112. All SAIKs and forensic toxicology kits are stored securely in locked forensic examination areas at each hospital facility where clinicians provide forensic examinations.

113. The coordination of access to increased numbers of SAIKs and forensic toxicology kits (up to 30 at a time) to avoid unnecessary delays for patients and staff, has improved significantly in recent times with the establishment of hospital police offices/beats at Logan and Gold Coast hospitals. My understanding was that QPS were reluctant to provide supplies of kits in larger quantities because of financial concerns in relation to 'SAIK wastage'.

[redacted]

a) In September 2015, I spoke with Acting Detective Senior Sergeant Barbara Briggs from Child Abuse & Sexual Crime Group (CASCG) in Brisbane who told me that SAIKs could no longer be accessed 'free of charge' from QPS South East Regional office as had been the arrangement previously. She said that her section was provided with the SAIKs by QHFSS and was responsible for disseminating them to CIBs/CPIUs around the State; FMOs were to access the kits from local police only.

See ***Exhibits***

CL-103 Emails between myself and Gold Coast CIB re CASCG communication re SAIKs (Sept 2015)

CL-104 Emails between myself and Logan CIB re SAIKs at Logan Hospital (Oct 2015)

b) In 2017, the Gold Coast service office sought assistance from Dr Griffin and Brisbane CFMU to access SAIKs for storage at Gold Coast and Logan examination facilities to reduce delays for patient/complainants and clinicians. Dr Griffin's view was that a supply of SAIKs at examination facilities was unnecessary and that police officers should provide SAIKs to clinicians on a case-by-case basis at the time of forensic examination. This was despite proven delays relating to the lack of availability of SAIKs, and criticism by Dr Griffin of the Gold Coast forensic service for the length of time taken by Gold Coast clinicians to conduct forensic examinations.

See ***Exhibits***

CL-98 Emails July 2016 re supplies of SAIKs to LGH L Burkin M Oresganin

CL-99 Emails Apr 2017 re supplies of SAIKs to GCUH D McDonald C del Santo

CL-100 Emails July 2017 re provision of SAIKs to GCUH A Griffin

CL-101 Emails July 2017 re supplies of SAIKs to GCUH S Jacobs M Ward

CL-102 Emails June 2017 re supplies of SAIKs to GCUH AC Brian Codd A Griffin

114. Between about 2014 and 2017, our service was accused of 'wasting kits' by Dr Griffin; he raised concerns that we were using SAIKs for the purposes of 'just in case' (JIC) forensic examinations (ie examinations without police involvement) prior to the instigation of the JIC initiative which commenced state wide in 2019. This is not the case; 'just in case' forensic examinations were not provided at our service until the Health Service Directive was issued re same in 2019. Clinicians providing services in the Gold Coast/Logan areas have only ever used SAIKs for police-requested forensic examinations. All completed SAIKs are handed by the examining clinician to the investigating police officer at the end of the forensic examination, and police issue a Field Property Receipt (FPR) for the SAIK. Both SAIK and FPR identification numbers are logged on the Gold Coast/Logan forensic service master register against the case file details.

Question 22 - Does your unit use the existing Queensland SAIK model in each SAIK examination? Why/why not? Do your staff regularly use additional equipment or consumables not contained in the standard kit? If yes, identify what further consumables are typically used and why they are used? Where do you source those further consumables from?

115. Clinicians employed by the GCHHS service use the existing Queensland SAIK for all police-requested forensic examinations, frequently supplemented with additional swabs, yellow-top containers and brown paper bags.

a) Additional forensic (dry) swabs may be required to ensure sampling from all relevant sites depending on scenario (eg oral, anal, vaginal) and that all visible potentially valuable material is retrieved from a site. If residual material remains after use of one swab at a particular site, a second or third swab may be taken from the same site.

b) Yellow top containers, tamper evident bags and brown paper bags of variable sizes may be required to collect items of potential forensic value such as tampons or debris/material retrieved from the vagina or anus that will not remain adherent to a swab, sanitary pads, underpants and other clothing items.

116. Additional forensic (dry) swabs used by our service are the same as those used for the Queensland SAIKs. They are purchased from BioMerieux Pty Ltd Australia, North Ryde, NSW; product code MW104-800.

See ***Exhibits***
CL-59 Photograph (1) of forensic swabs purchased to supplement SAIK.
CL-60 Photograph (2) of forensic swabs purchased to supplement SAIKs

117. Staff wearing personal protective equipment (PPE) transfer forensic dry swabs from the packets of 100 or so they are supplied in, to smaller clip-seal plastic bags which each hold 6-8 swabs. This process is carried out in the DNA sampling area on sterile plastic drapes. Clip-seal bags of extra swabs are stored in the forensic examination trolley for clinician convenience if/when required. This is an onerous process and the purchased swabs are not ideal (that is, not 'DNA-free', cotton-tipped with wooden stems) but are the same brand used in the current SAIKs. They are used as supplements to the standard SAIK swabs (6) when more than 6 swabs are required. The decision to use this process (rather than the opening of a second SAIK to access extra swabs) came about because of criticism in the past by CFMU Director/FSS of our service for 'wasting kits'.

118. Yellow top containers are used less frequently but may be necessary to collect certain items. These are sourced from hospital supplies.

119. Brown paper bags in various sizes for clothing items are sourced from Reward Hospitality at Yatala, Qld.

See ***Exhibit CL-61 Invoice brown paper bags for clothing items***

120. Tamper evident bags with unique numbering are purchased from Tamper Evident in Cheltenham, Victoria.

See ***Exhibit CL-62 Invoice tamper evident bags***

Question 23 - Do your staff also take a blood and urine sample from a sexual assault complainant? If so, is the equipment used in taking those samples also part of the SAIK model, or are they provided separately by Gold Coast HHS or QPS?

121. If forensic toxicology is requested as part of a sexual assault forensic examination by investigating police, typically if there is concern re 'drink-spiking' of the complainant, clinicians use standard forensic toxicology kits for this purpose; a separate kit with its own unique identifier is used for each sample; that is, one for urine sample and one for blood sample.

    See ***Exhibits***

    CL-32 Photograph (1) of Forensic Toxicology kit (2022)

    CL-33 Photograph (1) of Forensic Toxicology kit (2022)

122. Forensic toxicology kits are provided separately by QPS; sometimes police will bring them with the patient/complainant to the hospital but generally we use forensic toxicology kits ordered in bulk from QPS and stored in secure forensic examination rooms at each hospital facility.

Question 24 - Do your staff take a reference DNA sample from persons who are subject to a SAIK? If yes, identify what equipment is used to take that reference sample, and where the equipment comes from.

123. Clinicians at our service do not take reference DNA samples from patients having a SAIK completed because we do not have access to reference DNA sampling kits (saliva or blood) and have not received training in this sampling process.

124. Clinicians could collect reference DNA samples at the time of SAIK completion, if provided with clear guidelines and information about such aspects as how the result will be used, storage and destruction of sample etc. This information is necessary to allow clinicians to obtain informed consent from the subject prior to collection of a sample of their own DNA.

Question 25 - Identify what is meant by the phrase 'DNA minimising contamination model' (or similar). Do any other states adhere to this model, and if so, which ones. Does Queensland adhere to this model? Do you know if Queensland's adherence/non-adherence to this model affects the quality of biological material taken from forensic medical examinations in Queensland?

125. I am familiar with the term 'DNA contamination minimisation' in relation to the collection of evidence from living patient/complainants and suspects. As a forensic physician, it is relevant to clinical forensic processes, the environment in which forensic examination and evidence collection occurs and the forensic kits used to collect the evidence.

DNA contamination minimisation in relation to clinical facilities and processes for evidence collection

126. As far as I am aware, services providing forensic examinations which involve sampling in Victoria, NSW, SA, WA and ACT utilise clinical DNA contamination minimisation processes in line with RCPA Faculty of Clinical Forensic Medicine guidelines.
See ***Exhibits***
CL-63 RCPA FCFM Guideline for Cleaning Decontamination Forensic Examination Suites Guideline - Cleaning/Decontamination of Forensic Examination Suites
CL-64 Ballantyne KN et al (2015) DNA contamination minimisation – finding an effective cleaning method. Aust J For Sci DOI 10.1080/00450618.2015.1004195

127. I am unable to comment upon clinical forensic practices with respect to the DNA contamination minimisation for examination facilities in Queensland beyond the service I am responsible for.

128. In our service, DNA contamination minimisation processes are used:
   a) At the three hospital sites where clinicians conduct forensic examination of patient/complainants (Gold Coast University Hospital, Robina Hospital and Logan Hospital).

b) At the two police watch houses where clinicians conduct forensic examinations of suspects (Southport and Logan District watch houses).

129. I have no specific knowledge of the quality of biological material collected in forensic medical examinations in Queensland because I am not provided with this information in my role.

130. Any forensic sampling conducted without efforts to minimise DNA contamination has the potential to compromise the quality of biological evidence.

131. I would add that currently, clinicians at our service do their utmost to minimise DNA contamination when sampling suspects in police custody at watch houses by wearing full PPE and preparing examination surfaces in line with RCPA FCFM cleaning guidelines. However, the police watch house medical rooms in which suspect examinations are required to occur are not 'dedicated DNA sampling rooms' as we have at Gold Coast University and Logan Hospitals for complainant examinations. This situation is less than ideal.

132. In my view, forensic sampling of all subjects (complainants and suspects) should take place in dedicated DNA sampling rooms. However, because the same room should not be used to examine suspects and complainants, thereby requiring two separate DNA sampling rooms, two such rooms within a hospital to cater for this requirement has been difficult to achieve. The difficulties for police associated with the transfer of suspects in custody to non-custodial facilities for the purpose of forensic procedures is also a factor in decisions about where forensic sampling procedures take place.

DNA contamination minimisation in relation to SAIK design

133. I understand from communication with forensic colleagues in Victoria, NSW and WA that these states utilise sexual assault forensic kits developed with adherence to DNA contamination minimisation standards. HazPak (NSW, Tasmania and Victoria) and Sanax (WA) are the companies currently involved in development of SAIKs with the key clinical forensic services in these states.

See Exhibits

CL-65 Email advice from M Nittis re use of ISO certified kits in Australia (Sept 2022)

[redacted]

CL-66 Sanax Medical – ISO 18385 Certificate 2019

134. Forensic kits used to collect biological material for DNA detection should meet the 2017 ISO standard 18385 which outlines the requirements to minimise contamination on products used to collect, store and analyse biological materials.

135. I understand that HazPak is one of only nine companies globally who are accredited to ISO 18385: 2017. They were certified in 2020. Sanax which supplies kits to the Sexual Assault Resource Centre in WA is also certified to this standard.

136. Forensic kit items should be as 'DNA-free' as possible, with a single use design and provided to the clinician in a sealed tamper evident bag to ensure use of an intact kit for forensic evidence collection.

137. Forensic kits should ideally be complemented with so-called 'decontamination kits' for single use and containing necessary items to carry out a forensic examination such as paper bed sheets, paper gown, sterile drapes for surfaces, gloves, pens, scissors etc.

See ***Exhibit CL-67 Email to Lara Keller re VIFM contamination reduction kits with photographs (10 Dec 2021)***

138. All kits should be labelled with unique identifiers, preferably alpha-numerical.

139. Queensland does not utilise SAIKs which adhere to DNA contamination minimisation requirements. SAIKs are provided to Qld clinicians by police unsealed (that is, 'open') meaning that contents may fall out and there is potential for material to enter the kit before clinical use. Clinicians have no means of ensuring the kits have not been contaminated prior to their use.

See ***Exhibit CL-45 Vincent FHR. Inquiry into the circumstances that led to the conviction of Mr Farah Abdulkadir Jama. Victorian Department of Justice, 2010.***

<u>Just-In-Case (JIC) Kits</u>

Question 26 - Does your unit use JIC kits? When did the use of JIC kits commence?

140. Yes, our service provides forensic examinations using so-called 'Just in Case' (JIC) kits for people who are not ready to make contact with police to report a sexual assault.

[redacted]

141. The use of JIC kits commenced in August 2019 in response to a Health Service Directive (HSD) issued on 22 July 2019.

142. The initial HSD excluded 14-17 year olds from access to the JIC kit option, however an amendment to the HSD allowed 14-17 year olds with capacity to consent, to have a forensic examination (and JIC kit completed) without police involvement.

See ***Exhibits***

CL-68 Memo to HHS CEs (17 July 2019)

CL-69 Attachment 1 HSD Final (22 July 2019)

CL-70 HSQ Gold Coast HHS re inclusion 14-17 year olds JIC (12 Sept 2019)

Question 27 - How do you obtain these kits? Are they different to the standard SAIK model? If yes, explain how they are different.

143. 'Just in case' kits (or JIC kits) are sourced by clinicians at the time of JIC examination from the relevant hospital pathology department, usually from Central Specimen Reception (CSR).

144. JIC kits differ in external appearance from SAIKs with an opaque white plastic tamper proof bag (provided 'open' as with SAIKs) containing swabs, drop sheet and documentation, which is used to seal and secure collected evidence and paperwork for transfer to and storage at FSS. JIC kits include an additional pathology form and chain of custody form placed in a plastic pocket on the front of the opaque white plastic bag. It should be noted that they contain the same inadequate number of forensic swabs (6) as the SAIKs and no receptacles for other items with potential forensic value.

See ***Exhibits***

CL-71 Photograph (1) of JIC kit

CL-72 Photograph (2) of JIC kit

145. There is no provision for collection, transfer and storage of forensic toxicology samples or clothing items as part of the 'Just in Case' kit.

146. In June 2022, after toxicological questions could not be answered by the Prosecution (DPP) in relation to a case seen through our service, involving a woman who initially utilised the JIC kit option then later went on to report the incident to police, I raised the issue with the Head of Forensic Toxicology at FSS, Mark Stephenson. He was of the view that toxicological samples could be stored as part of a JIC kit if necessary. He told me that at the time of instigation of the JIC option in 2019, he had been led to believe that toxicology was not relevant for the JIC kit. The advice he received was clearly not obtained from a clinician involved in forensic examinations.

a) The sexual assault complainant in this matter was [redacted] she attended the Emergency Department on [redacted] and was forensically examined by Dr [redacted] at about [redacted] in relation to an incident which had occurred in the early hours of the [redacted]. She had not wanted to make contact with police at that time, so had a 'just-in-case' (JIC) kit completed rather than a SAIK. The JIC kit identification number was [redacted] Prior to the incident, Ms [redacted] had consumed alcohol and taken two alprazolam tablets. Toxicological samples (blood and urine) may be collected for up to 72 hours post-incident, but because the JIC option does not allow for transfer and secure storage of toxicology samples, they were not collected from Ms [redacted] at the time of forensic examination. Later, when Ms [redacted] decided to proceed with reporting the incident to police, they sought information about Dr [redacted] about Ms [redacted] level of intoxication, as a means of corroborating her inability to consent to sexual acts. I am uncertain if the matter has proceeded to trial or not.

See ***Exhibits***

CL-73 Email to Mark Stephenson re JIC kit contents add tox 6 Sept 2022

CL-106 Subpoena Dr Christine Mirakian, R v [redacted] 17 September 2021

147. This issue, I believe, highlights the importance of engaging with clinicians who are actively involved in doing forensic examinations when developing clinical forensic evidence kits.

[redacted]

Question 28 - When administering a JIC kit, do you or your staff supplement it with further equipment/consumables? If yes, provide details (or indicate if it is the same further equipment /consumables added when using a SAIK).

148. Yes, clinicians at our service supplement the JIC kits with swabs and receptacles for items of potential forensic value, in the same way as they do when using a SAIK, as outlined in my response to Question 22. Clinicians cannot however, add blood/urine toxicology samples or clothing items because JIC kit transfer and storage processes do not allow for this.

Question 29 - Should the content or design of the JIC kit be changed? If so, provide details and reasons for such a change.

149. The contents of the JIC kit should be the same as the 'ideal' SAIK, containing all necessary items to collect any material/items of potential forensic value, and allow for toxicology sample and clothing item collection, transfer and storage in the same way. Both SAIKs and JIC kits must be 'fit for purpose' for clinical practice and laboratory analysis and meet Australian Standard ISO 18385-2017 with respect to DNA contamination minimisation.

150. The concept behind the 'just in case' option for people who report sexual assault is that a person can have evidence collected if they are not yet ready to make contact with police. There is no basis for differential clinical evidence collection between the police SAIK and JIC kit.

Question 30 - Once a JIC is completed, who is it given to and where is it stored?

151. Completed JIC kits are lodged at hospital pathology departments (Central Specimen Reception or CSR) using a chain of Custody form to document any handling of the kit between examining clinician and CSR. See Appendix D in the Queensland Health document entitled *'For Laboratory: Potential forensic evidence "Just in Case" Forensic Examinations'*.

152. The process of transport and storage which occurs after the delivery of completed JIC kit to hospital CSR is outlined in the Queensland Health document entitled *'For Laboratory: Potential forensic evidence "Just in Case" Forensic Examinations'*.
See *Exhibit CL-74 For Laboratory: Potential forensic evidence 'Just in Case' Forensic Examinations*

Accused persons

Question 31 - Do you or your staff undertake forensic medical examinations on suspects or accused persons? If so, where are those examinations conducted? Do you consider the location at which those examinations are conducted affects the quality of the biological material sampled and/or the DNA results ultimately obtained?

153. Yes, clinicians at our service examine suspects/accused persons at the request of police. These examinations may involve examination for injury or collection of biological samples or both and take place in medical rooms at police watch houses.
154. We do not receive information about analysis results or the quality of biological material sampled from FSS, so I am unable to comment.
155. As previously outlined in paragraphs 131 and 132, the environment in which clinicians are obliged to collect evidence from suspects is less than ideal from a DNA contamination risk perspective.
156. Clinicians from GCUH Forensic Medicine endeavour to minimise DNA contamination when sampling suspects in police custody at watch houses by wearing full PPE and preparing examination surfaces in line with RCPA FCFM cleaning guidelines, using the same procedures as for sexual assault complainants. However, the police watch house medical rooms in which suspect examinations are required to occur are not dedicated to 'DNA sampling' as the rooms at Gold Coast University and Logan Hospitals are for complainant examinations.
157. In my view, forensic sampling of all subjects should take place in dedicated DNA sampling rooms. Unfortunately, because the same room should not be used to examine both complainants and suspects/accused persons, two separate dedicated DNA

sampling rooms would be required within a hospital for appropriate sampling; this is difficult to achieve. Police challenges with the transfer of suspects in custody to non-custodial facilities such as hospitals for the purpose of forensic procedures is also a factor in decisions about where suspect/accused person forensic sampling procedures take place.

Question 32 - Roughly how many forensic examinations on accused persons do your staff complete each year?

158. Annual figures for forensic examination of suspects/accused persons in Gold Coast/Logan:

Calendar year	Suspect forensic examinations
2021	20
2020	19
2019	16
2018	n/a
2017	28
2016	n/a
2015	35
Financial year	**Suspect forensic examinations**
2014/15	41
2013/14	37
2012/13	35
2011/12	37
2010/11	16
2009/10	35
2008/09	19
2007/08	27
2006/07	27
2005/06	29

Question 33 - What equipment/kit does your staff use to conduct these forensic medical examinations? If you do not use a SAIK when conducting forensic medical examinations,

explain why you do not use the SAIK. What document/booklet, if any, does a forensic physician in your unit complete when undertaking such an examination?

159. In Queensland, there is no forensic evidence kit designed for use when examining suspects/accused persons.

160. When sampling suspects/accused persons, clinicians at our service use forensic dry swabs (purchased from BioMerieux Aust Pty Ltd and prepared by staff as outlined in points 103 and 104), clear tamper evident plastic bags obtained from police (smaller version of that used for SAIKs), and documentation, sticker labels and body diagrams developed by our service.

See ***Exhibits***

CL-75 GCUH Suspect forensic sample form

CL-76 GCUH Suspect sampling sticker labels

CL-77 GCUH Toxicology form to accompany suspect samples

CL-78 GCUH Suspect examination body diagrams

CL-79 GCUH Suspect examination genital diagram

CL-80 Procedure for taking male genital swabs (CL)

161. If police request toxicology samples, we use the standard forensic toxicology kits as for complainants to blood and urine samples.

162. The completion of a clinical form to accompany samples and provide relevant information, document chain of custody for samples is appropriate clinical practice. Police understand and support this but have received negative feedback from the laboratory in relation to written input from clinicians.

See ***Exhibit CL-81 Email FSS QPS re suspect sampling documentation Oct 2019***

163. Clinicians at our service don't use the SAIK for suspect examinations primarily because the clinical documentation is designed for victim/complainants.

See ***Exhibit CL-82 FSS SAIK medical examination information form DNA***

164. Police do not associate SAIKs with suspect examinations and therefore do not provide these to clinicians prior to a suspect forensic examination.

165. We have been criticised in the past by Dr Adam Griffin/FSS for 'wasting SAIKs' and given they are not designed for suspect examinations, felt that use for this purpose could be viewed as problematic.

166. The SAIK could conceivably be adapted for use in both complainant and suspect sampling for sexual offence investigation, However, given the need to make these kits as 'user-friendly' as possible for clinicians who do these examinations relatively infrequently, separate kits for each type of examination is preferable.

Question 34 - Detail any knowledge you have of how the equipment used for accused person examinations in Queensland differs to the equipment used in other Australian states and territories?

167. I understand from communication with Dr Maria Nittis, Head of Department, Clinical Forensic Medicine at the Victorian Institute of Forensic Medicine (VIFM) that HazPak forensic kits are currently under review in Victoria. Victorian forensic clinicians are collaborating with HazPak to design complainant and suspect kits, each to be used in conjunction with a decontamination kit. Appropriate documentation proformas for each kit are designed and disseminated to examiners by forensic clinicians at the Victorian Institute of Forensic Medicine (VIFM).

See ***Exhibit CL-83 Email M Nittis VIFM re kits for suspect examinations (Sept 2022)***

168. I have no knowledge of suspect examination forensic kits used in other states or territories.

Question 35 - Do your staff take a reference DNA sample from accused persons when they conduct a forensic medical examination on that person? If yes, what equipment is used to take that reference sample, and where does the equipment come form?

169. No. We have never been asked by police to take reference DNA samples from suspects/accused persons.

Communication and feedback

Question 36 - Have you been criticised or been given negative feedback by any person in management at the CFMU, QH or other stakeholder agencies about how your unit conducts SAIKs or the equipment you use in conducting SAIKs? If so, provide details of the criticism (who made it, approximately when the feedback was made, and whether it is a fair criticism). If that criticism or negative feedback was provided by email or other documentary form, attach that correspondence.

Multiple swabs from single site

170. In 2016, I received an email from Abigail Houlding, A/Senior Scientist, Forensic DNA Analysis, FSS raising concerns re the number of swabs taken in SAIKs from our service. She acknowledged in her email that the number of swabs collected was at the discretion of the examiner, but said too many swabs impacted turnaround times for other casework. I felt uneasy about this given that other jurisdictions (including Western Australia and United Kingdom) routinely collect (at least) two swabs from each site. However, I modified my practice to collect only the number of swabs required to retrieve macroscopically visible material. By this I mean that if I collected, for example, one high vaginal swab but visible residual material remained in the high vagina after taking this swab, I took a second swab. I labelled swabs as '1' and '2' and endeavoured to record my rationale for the second swab in these cases. My primary concern during a SAIK is to maximise the potential for evidence collection.

See ***Exhibit CL-84 Email 2016 from FSS (Abigail Houlding) re SAIK swabs (Mar 2016)***

171. In 2019, I received an email from Dr Griffin about a member of my staff who had collected more than one swab from a genital site, in line with FFLM (UK) guidelines. I did not agree with his interpretation of the available resources (FFLM and RCPA) but forwarded his email to my team for their information.

See ***Exhibits***

CL-85 Email from A Griffin re multiple swabs (Oct 2019)

CL-86 Email to Gold Coast staff re criticism for taking multiple swabs (Oct 2019)

Triage and cut-off time limits for forensic examination

172. In May 2017, Dr Griffin sought to revise guidelines in Queensland for triage of requests for sexual assault forensic examinations based on so-called cut-off limits for detection of sperm/DNA. I was concerned that he was seeking to base important decisions re timing of forensic response to sexual assault complainants solely upon the likelihood of detection of biological material when the presence of genital injury to corroborate a penetrative act or bodily injury to corroborate a struggle between complainant and perpetrator is equally important to investigators.

173. Dr Griffin's suggestions did not appear to align with those of key services in other states and I was concerned that this non-alignment may lead to an adverse event. I believe that Queensland procedures should seek to align where appropriate and reliable with the practice of our peers. In my view, collaborative discussion at a national level with other clinical forensic services was an essential process before changing forensic response triage procedures.

See ***Exhibits***

CL-87 Email discussion CFMU re time limit triage forensic examinations (May 2017)

CL-87a Email A Griffin re DNA retention examination time limits (April 2017)

CL-88 VIFM Recommended Maximum Time for Routine Forensic Sample Collection

Question 37 - If any person in management from the CFMU, QH, or other stakeholder agency has provided positive feedback about how your unit conducts SAIKs or the equipment you use in conducting SAIKs, provide details (who made it and approximately when the feedback was made).

174. I cannot recall receiving any positive feedback from CFMU or FSS in relation to SAIKs collected or equipment used to collect evidence in sexual assault cases. On occasion,

forensic clinicians from Brisbane have sought advice from our service in relation to our protocols and procedures for clinical DNA contamination minimisation processes, which we have provided.

175. On occasion, investigating police will communicate SAIK analysis results to clinicians in our service, in relation to specific cases, primarily to seek advice about interpretation of a positive swab result at a particular body site. This is appropriate with regards clinical queries outside the expertise of laboratory staff, such as method of swab collection, description of anatomical site, comment on potential movement of material between sites, etc.

Question 38 - Have police officers or the QPS provided any feedback to you about having to take reference samples themselves? Who do you think should take reference samples, and why? Have you communicated with Dr Griffin about this topic; if so, explain the nature of your communication with him about this topic.

176. Some years ago, I was asked to take a reference DNA sample from a sexual assault patient/complainant by a police officer who was not aware that we were not provided with or trained in use of specialised reference DNA kits. I explained this to him, and since then, as I understand the situation, Gold Coast and Logan police perform this sampling at the time of complainant statement completion. This approach appeared to have some merit, as it meant that personal reference DNA sampling of complainants was not being carried out unless the investigation was to proceed.

177. Having said that, my view in relation to the issue of reference DNA collection from complainants was recently sought by FSS and I responded that I do not consider it problematic for clinicians to take these samples at the time of the SAIK, as long as clear information can be provided about what will happen to the sample and its analysis result, to permit clinicians to obtain fully informed consent from patients. Hospital clinical governance requirements also specify certain provisions around involvement of their staff in this type of sampling.

178. I have not communicated directly with Dr Griffin in relation to this topic but was present at a meeting of the Queensland Sexual Assault Interagency Guidelines Working

Group lead by the Department of Justice and Attorney General on 28 July, 2022 which he attended, where the issue of reference DNA samples was discussed.

See ***Exhibit CL-105 Handwritten notes made by CL during Queensland Government Interagency Sexual Assault Response Guidelines working group meeting 28 July 2022***

179. I later provided email advice re the wording of a paragraph about this issue in the Guideline document, at the request of acting Executive Director FSS Helen Gregg; I understand Dr Griffin was included in the email thread.

See ***Exhibit CL-43 Emails with FSS re proposed edit to SA interagency guidelines re reference DNA samples***

180. As outlined earlier in response to Question 24, my view is that reference DNA samples could reasonably be collected by clinicians at the time of SAIK collection. However, because the clinician would need to obtain informed consent from the sexual assault patient/complainant before doing so, they would require information and assurances in relation to processing of the sample, how long it would be kept for, where it would be stored, and whether there is potential for it to be included in the criminal DNA database

Question 39 - Does your unit or do your staff receive any communication or feedback from QHFSS or Queensland Police Service about the SAIKs you conduct in particular cases and the quality of biological samples that are taken in those cases?

181. QHFSS do not communicate or provide feedback about the analysis of SAIKs completed or the quality of biological samples collected to any of the clinicians in my service despite a number of approaches to FSS over the years to discuss the possibility of doing so and explain the benefits.

182. In or around 2007, I designed a sample feedback form template based on the SAIK feedback form in use in WA prior to 2004; I provided this to CFMU Director at the time.

See ***Exhibits***

CL-89 Draft Qld Sexual Assault Kit feedback form (2007)

CL-90 WA SARC Kit feedback form (2003)

183. In 2009, I emailed the CFMU Director to request consideration of sample analysis feedback again.

See ***Exhibit CL-91 Email CL to Director CFMU re sample feedback (2009)***

184. I am not aware whether FSS provides sample analysis/quality information to the Brisbane CFMU or Dr Griffin. If they do, it is not forwarded to clinicians at our service.

185. As outlined in response to Question 37, on occasion, investigating police will communicate SAIK analysis results to clinicians in our service in relation to specific cases, primarily to seek advice about interpretation of a positive swab result at a particular body site. This is entirely appropriate with regards clinical queries outside the expertise of laboratory staff such as method of swab collection, description of anatomical site, comment on potential movement of material between sites, etc.

186. Police do not and have never provided information to clinicians at our service in relation to the quality of biological samples collected.

187. Police routinely provide clinicians with Certificates of Analysis in relation to toxicological analysis of blood and urine samples they collect, for the purpose of interpretation.

Question 40 - Would you be assisted by the provision of such feedback? Why/why not? What type of similar feedback, if any, have you been given in past roles during your career?

188. As a forensic clinician, being informed about a positive or negative swab result or the quality of a sample collected, provides valuable feedback which can inform and improve future practice.

189. Clinicians working in 'therapeutic' medicine (as opposed to 'forensic' medicine) are used to receiving results for the tests they order; however most working in forensic medicine find it challenging not to receive any information about the analysis results of forensic swabs and other evidence they have collected.

190. In my experience of receiving laboratory feedback re forensic samples, namely in WA between 1995 and 2003, I found that provision of information to forensic clinicians about SAIK sample analysis:

a) Enhances and informs future clinical practice,

b) Provides a valuable opportunity for quality assurance,

c) Assists with clinical teaching, learning and skill development,

d) Has the potential to create a source of evidence-based information to inform decision-making about such questions as appropriate samples to collect, maximum timing for collection of samples etc.

e) Fosters a collaborative relationship between clinicians and laboratory staff with the potential for much-needed cross-discipline research in this area.

191. I believe that information-sharing between clinicians and laboratories can be carried out in such a way that legal evidentiary processes are not compromised.

Physical facilities

Question 41 - Describe the physical facilities or rooms at the Gold Coast HHS in which SAIKs are administered? Do you oversee the procedures used in cleaning those rooms/facilities? Provide details of what equipment is used and to what standard (if any) they are cleaned? Are the rooms secured?

192. Forensic examinations using SAIKs are carried out by GCHHS clinicians at three locations:

a) Gold Coast University Hospital (GCUH) Emergency Department (~100 per year)

b) Logan Hospital (LGH) Emergency Department (~ 70 per year)

c) Robina Hospital (RBH) Emergency Department (~25 per year)

193. GCUH and LGH have dedicated DNA sampling rooms within the Emergency Departments. These rooms remain locked when not in use and can only be accessed by clinicians and cleaners by swipe access key. The rooms are cleaned 'terminally' to HHS Infection Control standard after each examination and the room locked.

194. RBH has a specified room in the Emergency Department (not solely for forensic use) which is cleaned 'terminally' to HHS Infection Control standard prior to a forensic examination and locked until commencement of examination.

See Exhibits

CL-92 Email from Team Leader, Environmental Services, GCUH (15 Sept 2022)

CL-93 Diversey Divercleanse Hospital Grade Disinfectant - Ultimate Cleaning Products

195. A proposal to include a dedicated DNA sampling room at RBH Emergency Department has been submitted as part of RBH Emergency Department renovation.

196. The forensic service oversees cleaning procedures and documentation for the DNA sampling rooms. At GCUH and LGH, clinicians are responsible for requesting cleaner attendance immediately following the use of the room and all cleaners are required to complete a cleaning log book as well as a room entry register log. Cleaners at RBH are required to complete a cleaning log book after terminal clean of forensic room pre-forensic examination. Clinicians do not proceed with a forensic examination without checking that a terminal clean has occurred.

197. Prior to forensic examination and SAIK completion, examining clinicians conduct a 'pre-examination surface DNA clean' by wiping down all surfaces in the room with bleach, followed by sterile water after a period of 3-5mins, using low-lint paper cloths. This process is also used at the two sites where suspects are forensically examined and samples taken by clinicians (that is, Southport and Logan District Watch houses).

See ***Exhibits***

CL-94 Pre examination DNA clean GCFM (2019)

CL-95 ThermoFisher PDI Sani-Cloth Chlor - Technical Specification 201704

CL-96 ThermoFisher PDI Sani-Cloth TGA 227283 certificate class IIb

CL-97 Email from ThermoFisher re SaniCloth bleach content

Question 42 - Explain why you have adopted any cleaning standards referred to when answering the question immediately above.

198. The processes described in response to Question 41 have been adopted to ensure practice is in line with recommendations for DNA contamination minimisation in the following documents (also referred to in response to Question 25):

a) RCPA FCFM Guideline for Cleaning Decontamination Forensic Examination Suites

b) Vincent FHR. Inquiry into the circumstances that led to the conviction of Mr Farah Abdulkadir Jama. Victorian Department of Justice, 2010.

c) Ballantyne KN et al (2015) DNA contamination minimisation – finding an effective cleaning method. Aust J For Sci DOI 10.1080/00450618.2015.1004195

Other issues

Question 43 - Explain the change that occurred in around 2009 whereby persons conducting SAIKs no longer had to produce slides. Did that make the job of conducting a SAIK easier or more difficult. Do you consider this has, of itself, affected the quality of biological material collected?

199. I have addressed this issue in my response to Questions 16 and 17 at paragraphs 58-67.

Question 44 - Identify and detail any other concerns, criticism or feedback you have of the current Queensland SAIK model, the JIC kits or the current processes for collecting biological material for forensic DNA testing in sexual assault matters. Attach supporting documents if necessary.

200. I have nothing additional to include other than to re-state that I believe that:

a) While SAIKs and JIC kits must be 'fit for purpose' for both clinicians and laboratory staff, their design is rightly within the purview of clinicians. They should be developed collaboratively by clinicians and laboratories.

b) SAIKs and JIC kit production must meet ISO Standard 18385; 2017.

c) Feedback to clinicians re sample analysis and quality is an important quality assurance tool and has the potential to provide evidence-based information to inform SAIK development and continued improvement.

d) SAIKs and JIC kits should not differ in design; clinicians should be able to collect, the same evidence for transfer and storage when completing a JIC kit as is possible for a SAIK.

All the facts and circumstances declared in my statement, are within my own knowledge and belief, except for the facts and circumstances declared from information only, and where applicable, my means of knowledge and sources of information are contained in this statement.

I make this solemn declaration conscientiously believing the same to be true and by virtue of the provisions of the *Oaths Act 1867*.

TAKEN AND DECLARED before me at ## in the State of Queensland this ## day of ## [month] 2022

Gold Coast Hospital and Health Service

Guideline

Document ID GL1857

Care of Patients Aged 14 and above who have Sustained Reported Sexual Assault

Gold Coast Hospital and Health Service / Emergency Services

1. Purpose

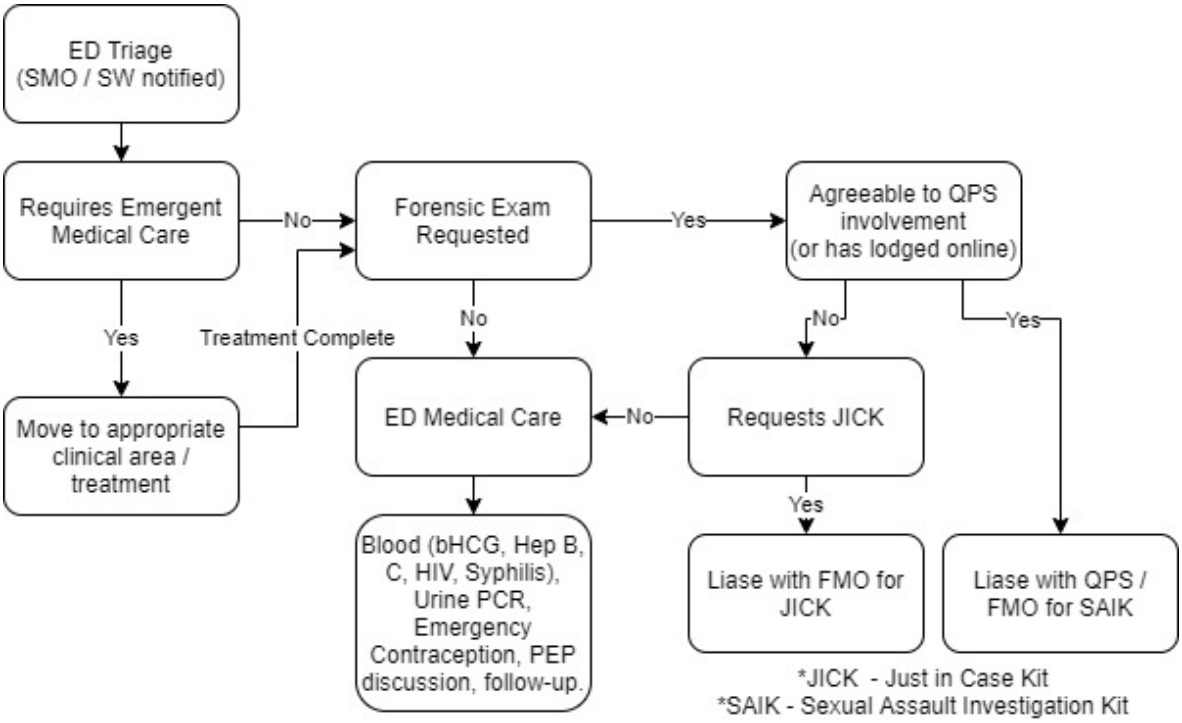
To provide patient centred care for patients aged 14 and above who have reported a sexual assault (SA). This is to facilitate trauma informed psychosocial interventions and appropriate medical assessment and management in a timely manner. The management includes forensic evidence collection when required

2. Scope

This guideline applies to all Clinical Staff within the Emergency Departments (ED) of the Gold Coast Hospital and Health Service (GCHHS).

3. Guideline for Care of Patients Aged 14 and above who have Sustained Reported Sexual Assault

This guideline has two parts and the overall process is summarised by the flowchart below:



Section 3.1 describes usual ED reception of all patients who present for care. It describes triage and streaming of patients to ensure urgent medical care is prioritised. It also describes when Forensic Physician (FP) assessment is requested.

Section 3.2 describes routine ED care for those patients who do not wish to undergo forensic examination. This aims to provide appropriate management including pregnancy prevention, prevention of disease transmission, appropriate medical follow-up and psychosocial support (PSS) in a timely manner for those who do not proceed to the Forensic Physician (FP) assessment.

3.1. Initial Triage, Referral and Management in ED of reported Sexual Assault

3.1.1. At triage patients requiring urgent ED Medical Assessment are identified through usual triage process and streamed to the appropriate area. The consultant on duty (or registrar overnight) should be notified to facilitate these assessments.

3.1.2. In unstable patients or patients with suspected major injuries, clinical care by hospital staff should proceed as the immediate priority.

3.1.2.1. For patients with apparent minor vaginal or rectal bleeding likely from reported assault, ED medical assessment may be by history and review of vital signs and general status, with intention to avoid loss or contamination of evidence/DNA.

Senior ED consultant advice and discussion with the FP may be required.

3.1.3. Internal examination for evidence collection is best done by an FP and using the appropriate forensic kit.

Combined FP and gynaecology team assessment may be indicated in occasional stable patients or in cases of doubt regarding severity and need for surgical care (e.g. bleeding genito-anal injury or possible intra-vaginal/intra-rectal foreign body).

In such cases, the ED consultant and gynaecological team may request FP involvement for evidence collection. The aim is to perform a single intimate examination for assessment, evidence collection and treatment purposes wherever possible.

3.1.4. All patients should be referred to the ED Social Worker (SW) by triage nurse for psychosocial intervention upon arrival/triage.

3.1.4.1. SW must also be advised if they are currently requiring immediate ED medical care. Social work is available at GCUH 24 hours a day.

3.1.5. The ED social worker will have a trauma informed approach and give information regarding options for the patient.

SW have a process, as described in the 'Quick Reference Guide' (Appendix 6); these include:

1. Referral to Queensland Police Service (QPS) and FP
2. Referral to ED medical officer (EDMO) for medical care
3. Referral to Gold Coast Centre Against Sexual Violence (GCCASV)
4. Other Counselling

Patients may require one or more of these services.

3.1.6. If SW is not available at Robina (after hours), nurse in charge and clinicians who require telephone advice regarding SW process please contact:

GCUH ED SW (24 hour service) on 5687 5817, 5687 7992 or via switchboard.

A referral to SW can be made via Overnight Referral Book held at triage for follow up providing consent has been obtained.

3.1.7. All patients will remain under the care of the ED throughout their stay.

3.1.8. The FP service is considered a consultation service for patient centred care of sexual assault (SA).

Patients requiring FP examination will remain in ED except for the time of FP examination. This will occur in a designated forensic examination room to reduce potential for DNA contamination.

3.1.9. If the patient is wearing clothes from the time of incident, please encourage the patient to remain in their clothing and ask that they await the FP prior to showering.

3.1.9.1. Should the patient need to pass urine, the first catch may be valuable forensically (toxicology, DNA).

Police will typically provide an appropriate forensic suit if required.

3.1.9.2. Cases that present >7 days after alleged sexual assault will in most instances not benefit from evidence collection by the FP.

In such cases Emergency Department Medical Officer (EDMO) assessment may be more appropriate. Cases of doubt can be discussed by the ED medical team with the FP on call.

3.1.10. FP response is expected to occur within 2 hours of request for forensic examination.

An FP assessment typically includes:

- injury documentation,
- collection of samples;
- and other evidence and medical care after SA.

3.1.11. In discussion with and while awaiting FP, collection of blood and urine samples for testing as below, can help:

- Reduce the patients ED length of stay,
- provide valuable information about Hep B and pregnancy status,
- and assist with risk stratification on arrival of the FP.

These can also be collected by FP at time of forensic examination if police are requesting toxicology samples to avoid multiple venepuncture.

3.1.12. Some patients will opt <u>not to proceed</u> with forensic examination after speaking with police; they should be offered ED medical assessment described below in 3.2, alternative follow up should they decline.

3.1.13. Forensic examination following police contact will always utilise the more comprehensive Sexual Assault Investigation Kit (SAIK), not the Just In Case Kit (JICK) and will be handed to QPS.

The patient retains option not to proceed with police process.

3.1.14. Those seen by the FP would be anticipated to receive good medical care as appropriate after sexual assault.

3.1.15. The FP will complete a brief record of the attendance in the GCHHS medical record.

3.1.16. The FP may need assistance to provide that care.

The FP will communicate (verbally and in writing) appropriate orders in relation to further management of the patient by ED staff.

3.1.17. ED Nursing staff will assist with a chaperone if required, and collection of non-forensic pathology samples if required as ordered by the FP.

3.1.18. ED Nursing staff can facilitate drug administration if this is charted by the FP.

3.1.19. The FP may, after assessment, request ED medical assistance if unexpected findings require emergency care.

This handover of care should be documented by the FP.

The intent of the above is to ensure appropriate patient-centred care and avoid any unnecessary repeated assessments by numerous clinicians.

All staff are also reminded of their mandatory reporting obligations with respect to suspected sexual offences against children (person aged under 16 years old or a person under 18 with an impairment of the mind.)

Refer to PRO1518 Caring for Children undergoing Sexual Abuse/Assault Examinations for patients under the age of 14.

3.2. Medical Management for reported Sexual Assault where FP assessment is not performed.

For those patients who remain under ED care (i.e. not for FP/QPS intervention), the ED medical officer will do the following.

NOTE: Below is a summation/checklist and please see the appendices for full detailed information.

Assess:

- Assess and treat any injury.
- Document alleged incident and injuries in detail.
- Assess risk for HIV: Post Exposure Prophylaxis needs to be considered if assailant was known to be HIV positive, was known to be a male who had sex with males, or was from high risk country such as Africa, SE Asia or PNG. Other factors increasing risk include bleeding genital injury, multiple perpetrators.
- Assess risk of Hep B: Prior immunisation status?
- Assess risk of pregnancy: Prior contraception?
- Assess risk of sexually transmitted infection.
- Assess medical Hx, medications and allergy.

Investigations:

- STI baseline screening
  - Urine Chlamydia / Gonorrhoea PCR
  - Hep B, Hep C, HIV, Syphilis serology.
- FBC ELFT if considering PEP.
- BHCG if possibly pregnant.
- All other testing may be deferred until follow up.

Management:

a) Consider HIV risk: If high risk HIV exposure or uncertainty contact ID physician for advice. If PEP commenced, starter packs (A or B) located in medication rooms in Minors (GCUH) and Acute (Robina), contain the first 3 days treatment only. Those started on PEP must be urgently referred to GC Sexual Health Clinic for follow up and to access remainder of PEP course - see details in Appendix 1

b) Consider Hepatitis B Immunity - Hep B vaccination; if not vaccinated or vaccination status unknown, give first dose Hep B vaccine. (Consider Hep B immunoglobulin at follow up before 72hrs if proven not immune and high-risk exposure cases) – see details Appendix 2

c) Consider Emergency Contraception – unless good contraceptive cover, consider Levornogestrol 1.5mg orally as a single dose, up to 72hrs post reported assault, or if 72hrs -120hrs post incident - consider Ulipristal acetate – see details Appendix 3

d) Consider STI prophylaxis if anticipate unreliable to follow up – see details Appendix 4

e) Consider Tetanus Prophylaxis – ADT if indicated

f) Arrange appropriate follow up – see detailed recommendations Appendix 5.

Appendix 1

Assessing need for HIV prophylaxis

The risk of HIV following sexual assault in Australia is very low. Despite the low likelihood of infection, HIV remains a concern for victims and should be discussed. Giving a realistic estimation of risks may provide reassurance to the victim.

HIV prophylaxis is infrequently required following sexual assault but should be considered if assailant was known to be HIV positive, was known to be a male who had sex with males, was a known IVDU or was from high HIV risk country such as Sub-Saharan Africa, SE Asia or PNG. Known homosexual IVDU as the perpetrator are a potential high-risk group also for HIV. Transmission risk is also higher if the SA resulted in bleeding genito-anal injury. *Refer to ASHM guidelines for table summarising quantitative risks in different sexual activity scenarios.

Routine baseline status for HIV should be undertaken. For pre HIV counselling please refer to the HIV-pre and post-test counselling information and patient brochures located at https://www.health.qld.gov.au/clinical-practice/guidelines-procedures/sex-health/hiv-aids

For high risk cases or any concerns, discuss each case individually with on call ID consultant.

Post exposure prophylaxis starter drug packs are kept in treatment room in ED Minors (GCUH) and Acute (Robina) – these are authorised by ID consultant who will advise which starter pack to use. Most will require PEP Pack A (two drug regimen) – please ensure you follow correct procedures in its administration and documentation. They must be instituted within 72hrs. Follow up of these patients is as an outpatient to GC Sexual health Clinic.

Common side effects are nausea, headaches, lethargy (up to 1/3 of patients cease these drugs before completion due to side effects) More serious side effects include liver toxicity. Baseline FBC and ELFT are required before starting.

<u>PEP Drug Regimen</u>

PEP Pack A: (2-drug regimen)
Tenofovir 291mg/ Emtricitabine 200mg. Dose: 1 tablet once daily

PEP Pack B: (3-drug regimen)
Tenofovir 291mg/ Emtricitabine 200mg. Dose: 1 tablet once daily
PLUS
Raltegravir 400mg BD. Dose: 1 tablet TWICE daily.

Appendix 2

Hepatitis B risk assessment and management post sexual assault

If Immunised – pathology testing only to confirm immunity and review and follow up of Hep B status. This may be done at follow up.

Hepatitis B Immunoglobulin is not routinely required.

No immunisation or partial immunisation -

If incomplete immunisation then give a booster.

If no prior immunisation –

Start immunisation for Hep B plus recommend further vaccination at 1month and 6 months. Also, consider 400 units IM Hepatitis B IG in a non-immune patient within 72 hrs particularly if exposure to member of high risk group for hepatitis B (Indigenous, men who have sex with men, injecting drug user, person from countries where hepatitis B is endemic). Most effective within 24 hours, but can be delivered up to 14 days post assault. A repeat Hepatitis B IG is also required at one month. Gold Coast sexual health clinic is happy to provide this service. GP can alternately provide this.

Follow up is necessary as repeat Hep B vaccination is required at 1 month and 6 months.

Appendix 3

Emergency Contraception post sexual assault.

If patient has good effective contraception this is not required e.g. Implanon, Mirena coil in situ, no missed OCP pills in last menstrual cycle Discuss benefits of morning after pill. Generally very safe and if any risk of pregnancy should be given.

If indicated, Levornogestrol 1.5mg orally as a single dose, as soon as possible up to 72hrs following event.
(ONLY EFFECTIVE IF USED WITHIN 72 HOURS (3 Days) OF ALLEGED ASSAULT)

More effective the earlier it is used. Consider offering oral antiemetic if patient known to have nausea with the drug, however very few (1.4 – 5.0%) patients vomit with the progesterone-only emergency contraceptive and antiemetics are not routinely recommended.

If presentation is >72hrs and less than 120hrs an alternate Ulipristal acetate is likely more effective. It can be obtained by private prescription at cost approximately $50. It is contraindicated in patients with liver disease, asthma requiring steroids, with breast feeding and less effective if using antacids or Proton Pump inhibitors.

Advise pregnancy test if next period late or different from normal.

Appendix 4

Prophylaxis of Sexually Transmitted Infection post sexual assault

Risk of STI such as chlamydia, gonorrhoea and trichomonas is overall low. Options of treatment prophylactically in ED or STI screens in 2 weeks to determine need should be considered depending on patient demographics, anticipated patient compliance and patient choice. This patient group are reported to have low attendance at arranged follow up appointments so opportunistic treatment should be considered in ED.

Chlamydia is the most frequently encountered STI that would be amenable to prophylaxis. Prophylaxis should be given in the ED if it is difficult to ensure compliance by follow-up of patient.

Azithromycin 1g orally stat.

These patients still require follow up STI screening with a urinary PCR at 2 weeks post SA as the above does not prevent other infections.

Other bacterial STIs have a very low prevalence on the Gold Coast. For high-risk or complex exposures (e.g. multiple assailants, assailant from population group with high rates of STI), contact Gold Coast Sexual Health Service (07 5576 9033) for advice or if after hours give:

Ceftriaxone 500mg IM with 2mls 1% lignocaine / Ceftriaxone 500mg IV stat - same if pregnant

PLUS

Azithromycin 1gm orally stat - same if pregnant

Appendix 5

Follow Up

All patients should be referred for follow up including pathology results and recommended ongoing testing. Most patients are suitable for medical follow up with their general practitioner.

Patients with more complex or high-risk exposures should be referred to Gold Coast Sexual Health Clinic for follow-up, as should patients with concerns about confidentiality or who require access to a free service.

Please ensure you complete a letter to the sexual health clinic in Southport and provide the patient with the clinic number (07 5576 9033) these will be available in the sexual assault pack. They also have a website https://www.goldcoast.health.qld.gov.au/our-services/sexual-health

Patients who are commenced on HIV post-exposure prophylaxis should be urgently referred to Gold Coast Sexual Health Service clinic for ongoing supply of medication and specialised management of antiretroviral drugs.

SW will recommend appropriate Sexual Assault Service and other psychosocial services.

Patients to be advised of QH 24hour sexual assault counselling help line – 1800 010 120. Local options including Gold Coast Centre Against Sexual Violence (GCASV) 07 55911164 and website www.stopsexualviolence.com should be provided. Additional contacts are available from https://www.casv.org.au/links/. Resources for counselling including an Assisted Referral Form where we refer patients to Gold Coast Centre against sexual violence with their consent. These are located in the Sexual Assault Pack. The sexual assault pack is located in the social work resource folder in triage reception of both EDs.

General literature from the sexual assault pack should be provided.

If the patient agrees please leave a referral for social work to follow up the next morning in SW referral book at triage desk to ensure trauma informed psychosocial care.

Appendix 6

Quick Reference Guide

A. Patient presents with Police

Required: Routine ED triage
Refer to Social Work
Police call Forensic Physician (FP) to request forensic examination - (QPS SAIK)

Option: *QPS involved means process is SAIK,* ***cannot be JICK***

B. Patient attends after talking/making contact with Police (e.g. referred following attendance at police station, arrived by QAS after police attendance at scene, online QPS report - not ARO) **but police are NOT at the ED with patient.**

Required: Routine ED triage
Refer to Social Worker
SW contacts Police to attend
Police contact FP to request Forensic Examination

Option: *QPS involved means process is SAIK,* ***cannot be JICK***

C. Patient presents to ED without prior contact with Police.

Required: Routine ED triage
Refer to Social Worker
Social Worker discusses the following options with patient:

1. Healthcare response only – no QPS no forensic examination
2. Forensic examination – QPS involvement (SAIK)
3. Forensic examination – No QPS involvement (JICK)

➡ **If patient opts for forensic examination**

Required: SW to complete Forensic Examination Pathway Consent form for those patients who present without Police
(insert date of examination; copy for patient, copy for ieMR and copy for FP)

➡ **If patient opts to discuss with Police**

Required: SW to call QPS to attend
QPS contact FP to request forensic examination (using SAIK)

or Patient may decide not to have forensic examination following discussion with QPS

or Patient may have forensic examination via QPS Pathways (SAIK) and decide not to proceed later (patient contacts QPS direct)

➡ **If patient does not want QPS involvement**, but requests forensic examination

Required: SW calls FP to request 'just in case' forensic examination (using JICK).

Please note:
Contact with QPS can only be made with patients consent – use Sexual Assault Forensic Examination Pathway consent form or document clearly in records.
Any involvement with QPS necessitates completion of police SAIK – not JICK.

SAIK = Sexual Assault Investigation Kit JICK = Just in Case Kit

INFORMATION TO SUPPORT DISCUSSION ABOUT FORENSIC EXAMINATION PATHWAY CONSENT

Informed Consent to Sexual Assault Forensic Examination

Sexual assault forensic examination:

The purpose of a forensic examination is to document any potential injuries and to obtain swabs for DNA analysis to contribute to a police investigation. The parts of the body examined for injuries and the sites of sample collection depend on the information provided by the patient. The forensic doctor only needs enough information about what happened to guide the examination process and does not require great detail.

Forensic examination for police reporting pathway:

Any information provided as part of the forensic examination will be made available to the police to assist with the investigation process.

The patient can change their mind at any time in the future by letting police know that they do not want to proceed.

Forensic examination for non-police reporting pathway
(so-called 'just in case' option):

If the patient is reluctant to talk to police at time of presentation, a forensic examination can be done to collect evidence for a police investigation at some point in the future. Information and samples will not be provided to police.

Forensic examination does not provide all the evidence police need to proceed with an investigation. Without police involvement, important evidence may be lost: for example:-

- witnesses cannot be interviewed
- clothing and toxicology samples cannot be collected
- crime scene assessment cannot occur
- CCTV cannot be accessed

This may make it more difficult to obtain sufficient evidence to support future criminal proceedings. There is also a small chance that samples may deteriorate over time.
Any DNA evidence that is collected without police involvement will not be tested but will be stored for a period of twelve months before being destroyed. The patient must attend a police station before this time if they change their mind and wish to proceed with a formal police report.

The decision to undergo a forensic examination or not rests entirely with the patient.

DO NOT WRITE IN THIS BINDING MARGIN

Just In Case
Forensic Medical Examinations

Important Considerations

- A forensic examination is best completed within 72 hours of the assault. If you present outside this time, there may not be sufficient evidence present to warrant an examination.
- If an examination is completed, samples will be kept for 12 months, after which time they will be disposed of. Just In Case samples are not tested.
- The JICK gathers a smaller number of forensic samples and may reduce your case options as opposed to a full forensic medical examination.
- It is your responsibility to contact police if you wish to make a formal complaint.
- By delaying a police investigation, other evidence may be lost which will impact the future success of any complaint.
- Record details of the assault to help you remember if you wish to speak with police in the future.

Contacting Police

If you decide to make a formal complaint to police you can do so by contacting PoliceLink on **131 444** or by attending your local police station.

Additional information about police reporting options can be found on the QPS website: **www.police.qld.gov.au**.

IN CASE OF EMERGENCY:
CALL QUEENSLAND POLICE ON 000

FOR NON-URGENT MATTERS:
CALL POLICELINK ON 131 444

Other important information

Just In Case

Forensic medical examinations: your rights and choices

Gold Coast Health
always care

Queensland Government

Sexual assault is a crime

Sexual assault is any unwanted or forced sexual act which a person does not consent to. This includes any sexual behaviour which makes a person feel threatened, frightened or uncomfortable.

Sexual assault can happen to anybody. It is never the victim's fault. Sexual assault is about power and control. In many cases, the offender is known and trusted. This includes a family member, close friend, or neighbour.

Queensland Health recognises the serious social, emotional, medical and legal impact a sexual assault may have and recognises the importance of victims being provided with:

- dignity and respect
- confidentiality and privacy
- timely and appropriate service
- information about legal rights, options and processes in a non-judgmental and sensitive manner, heard and supported.

Your Options

Deciding what to do can be difficult. Queensland Police Service strongly encourages anyone who has experienced a sexual assault to contact them to discuss the available reporting and support options.

As a victim of sexual assault, you have several reporting options available to you. These include:

1. Reporting the assault to police, which typically includes a forensic medical examination and initial interview at the hospital. You will be supported by a social worker during this process and informed about what happens in a forensic examination and police investigation.
2. Requesting to have a forensic examination to occur "Just In Case" you want to report to police in the future.
3. Providing police with details of the assault anonymously through the Alternative Reporting Option (ARO). No action will be taken but your information may assist police strategies to target offenders and reduce repeat offending. https://forms.police.qld.gov.au/sexassaultsurvey
4. Choosing not to report the assault in any way.

Whatever decision you make, you will always be provided with the necessary medical care as well as referrals to counselling and support services.

Just In Case Forensic Medical Examinations

You may be uncertain about making a complaint and not feel ready to speak with police. It can be very difficult to make decisions after you have had a traumatic experience. If you feel undecided about reporting the assault to police but might want to do so at a later time, a 'Just In Case' examination may be available.

If you choose this option, a forensic medical examination will take place and any samples collected will be stored by Queensland Health's Forensic and Scientific Services. These samples will not be tested unless you proceed with a formal police complaint.

You will need to sign a consent form that you understand that your sample

- will be stored by Queensland Health
- will only be sent for testing and provided to police if you proceed with a complaint to police
- will be destroyed after 12 months if no complaint is made.

If you select the Just In Case Examination, you may wish to record the date of the examination and place of examination for your records below:

_____

_____

What is a Just In Case Forensic Medical Examination?

You will be asked to briefly describe what happened to you and then a physical examination will be done to assess any injuries and collect samples.

It is an intimate examination undertaken by a specially trained doctor or nurse.

A Just In Case Kit (JICK) is used to collect samples. The JICK will be handled sensitively and securely to ensure it can be used as evidence if you do wish to proceed with a police complaint at a later time.

Support Following Sexual Assault

Gold Coast Centre Against Sexual Violence
The Gold Coast Centre Against Sexual Violence (GCCASV) is a free, confidential service for women who have experienced sexual violence at any time in their lives. It provides professional crisis support and counselling along with ongoing support through therapeutic and educational groups. Your privacy and choices will be respected at all times.

CONSENT FOR EXAMINATION

- This examination is for medical purposes and to gather evidence that might inform a police investigation
- The examiner will explain each part of the examination and you can decline any part of the examination at any time
- Information provided and examination findings may form the basis of a report to police
- The information provided with your consent, will be stored securely by the Victorian Institute of Forensic Medicine (VIFM)
- Information (including images) may be viewed by other VIFM staff for purposes of peer review or by authorised staff in accordance with VIFM's privacy policies
- There is no guarantee that any of the findings / evidence collected will benefit your case
- Information and evidence collected will be handed to police (if you consent to this) and may then be taken to a forensic laboratory for testing
- The information that you provide, the examination findings and any other evidence gathered may be used in court
- Undertaking this examination does not oblige you to continue with police or legal action

I consent to:	Tick if appropriate	Initial
A physical examination	☐	
Collection of forensic samples	☐	
Release of information / samples to police and consent to have those samples tested	☐	
Sharing of any information with relevant agencies with regards to either my health or investigation of the alleged incident	☐	
The use of non-identifying data for purposes of teaching and education	☐

This is a Just in Case (JIC) Assessment ☐

CONSENT FOR IMAGING

- The best way to document injuries is to provide a written description, draw them on a diagram and image them.
- Any images that are taken, with your consent, will be stored securely by the Victorian Institute of Forensic Medicine (VIFM).
- Images may be viewed by other VIFM staff for purposes of peer review or by authorized staff in accordance with VIFM's privacy policies
- Any images collected may be sent to police as part of the evidence collected from your examination.
- Images may subsequently also be viewed by lawyers, judge, jury (or other parties legitimately involved in any subsequent court case / investigation)
- Even if you consent to images being taken, you can choose to not have images taken of certain parts of your body. You will let the examiner know and this will be noted

I consent to:	Tick if appropriate	Initial

Subject: FW: Contamination reduction kit
Attachments: DSC_0119.JPG; DSC_0120.JPG; DSC_2764.jpg; DSC_3565.jpg; Gloves.pdf.jpg; Outer kit.jpg

Lara,

Just for your information, these are the sort of kits being used in other states for clinical forensic examinations involving sampling (Vic and NSW at least).

They allow forensic sampling to be done when there is no dedicated stocked clinical forensic sampling room managed by a CFM service as we have at GCUH and Logan Hospitals. Everything necessary is included for the clinician; essentially a SAIK or Offender Sampling Kit is used together with a DNA contamination reduction kit (sheet, gown, surface covers, pens etc) for each examination.

As discussed there are many problems with current SAIKs in Qld (unsealed, contaminated swabs provided, wooden swab sticks with potential to break) and we have no offender kit at all. The potential for contamination is significant especially when examinations are carried out in an ED without a dedicated service with an understanding of the DNA contamination issues.

I understand VIFM are currently negotiating with HazPak (based in Dandenong, Vic) to purchase these kits for their CFMU.

Cathy

STATEMENT OF JACQUELINE JANE THOMSON

I, **Jacqueline Jane Thomson, Assistant Director of Nursing,** of 51 Herschel Street, Brisbane do solemnly and sincerely declare that:

Question 1 – State your full name and current position/title at Queensland Health (QH).

1. Jacqueline Jane THOMSON, Assistant Director of Nursing, Clinical Forensic Medicine Unit, Forensic and Scientific Services.

Qualifications and experience

Question 2 – List your tertiary qualifications, the year you obtained them, and the institute from which the qualifications were obtained.

2. My tertiary qualifications are as follows:

- 2022 - Master of Business Administration candidate - Griffith University, Queensland
- 2021 - Introduction to the medical and forensic management of adult sexual assault - NSW Education Centre Against Violence
- 2015 - Graduate Certificate in Policy Analysis - Griffith University, Queensland
- 1996 - Bachelor of Nursing (Post-Registration) - Queensland University of Technology
- 1994 - Midwifery Certificate - Royal Women's Hospital, Queensland
- 1991 - General Nursing Certificate - Royal Brisbane Hospital, Queensland
- AHPRA Registration No: NMWOOO1439881 - Registered Midwife (Qld)
- AHPRA Registration No: NMWOOO1439882 - Registered Nurse (Qld)

Question 3 – Detail your work history since you graduated from university.

[redacted] [redacted]

Jacqueline Jane Thomson

3. I am a senior nurse and midwife and have worked in Queensland Health for over 34 years. I have worked across rural and metropolitan settings with expertise in tertiary and primary level nursing and maternity care. For the past 14 years, I have worked in various units within the Department of Health in middle and senior management roles and have achieved many successes in the development, implementation, and evaluation of major legislative reform, as well as state-wide programs of work and projects regarding the improvement in the delivery of healthcare services.

Queensland Health	34 years and 3 months		
	Clinical Forensic Medicine Unit, Forensic and scientific services	March 2020 - current	Assistant Director of Nursing
	Office of the Deputy Director General, Clinical Excellence Queensland	August 2018 – March 2020	Manager
	Healthcare Improvement Unit, Clinical Excellence Queensland	October 2016 – August 2018	Manager

Question 4 – Detail your appointments to any boards and/or committees. Include the year appointed, the year you ceased your position on the board or committee, and the purpose of the board or committee.

4. Not applicable.

Question 5 – Attach a current CV.

5. Please see Exhibit JJT-1.

[redacted] [redacted]

Jacqueline Jane Thomson Witness

Your role and unit

Question 6 – Provide an overview of your responsibilities, identify the unit you work in, and identify the role and function of that unit.

6. In my role, I:

- Provide high level contemporary, strategic, operational, and professional nursing leadership and management to Clinical Forensic Medicine Unit nursing personnel that provide healthcare at the Brisbane City Watchhouse;
- Work collaboratively with internal and external stakeholders to shape corporate and clinical governance within the Brisbane City Watchhouse;
- Administer the Sexual Assault Nurse Examiner Program including, but not limited to professional support, system support, education, research, and professional leadership;
- Utilise clinical expertise when providing sexual assault policy advice to the Minister, the Director-General, Deputy Director-General, senior departmental executives and stakeholders that may have significant political, community and business impacts; and
- Lead in facilitating initiatives and outcomes of the SANE-FNE Community of Practice to support professional, clinical, and organisational imperatives for Hospital and Health Service Sexual Assault Services.

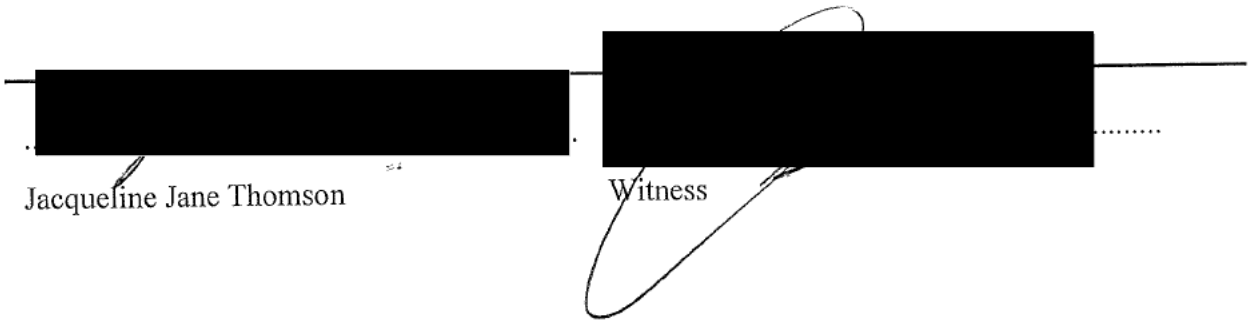
7. I work within the Clinical Forensic Medicine Unit (CFMU), Forensic and Scientific Services located at 51 Herschel Street, Brisbane City QLD 4000.

8. The role of CFMU is to provide medicolegal services for the State of Queensland. The scope of CFMU includes:

- examining victims and alleged perpetrators in criminal investigations at the request of the Queensland Police Service;

- providing state-wide education and 24/7 support to clinicians performing adult sexual assault forensic examinations;
- overseeing the sexual assault nurse examiner (SANEs) program;
- providing advice to the Queensland Police Service and the Queensland Ambulance Service around Natural Causes Deaths;
- medicolegal reporting and statement writing for criminal matters including:
  - documenting and interpreting injuries of victims of crime and alleged offenders
  - interpreting toxicology reports
  - assessing clinical effects and toxicology of alcohol and drugs
  - performing traffic medicine assessments (fitness to drive, drugs and driving, medical conditions and driving)
  - assessing medical fitness to appear in court or at an interview;
- medicolegal reporting and statement writing for the Coroners Court of Queensland including:
  - reviewing healthcare-related deaths
  - preparing reports for complex death investigations
  - interpreting post-mortem toxicology results;
- providing expert evidence to the courts; and
- providing healthcare advice to Queensland Police Service watch houses.

Question 7 – Outline who you report to, who reports to you, the staff you are responsible for and their positions, roles, and responsibilities.



Jacqueline Jane Thomson

Witness

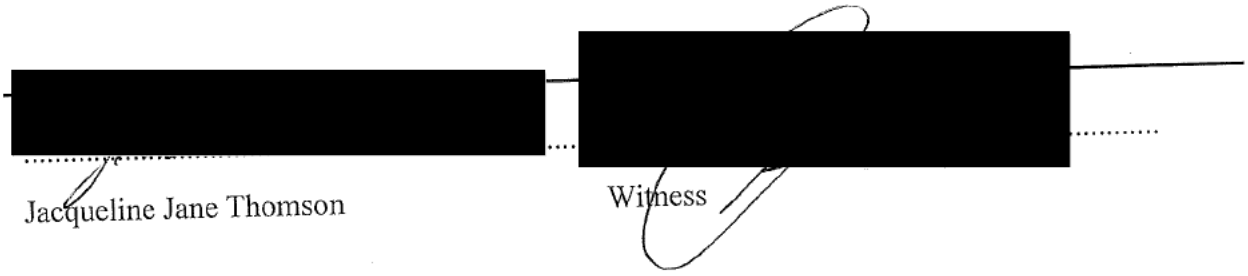
9. I report operationally to Dr Adam Griffin, Director, CFMU. I am budgeted for 3.25 FTE nursing positions. I have a head count of 5 nursing personnel (permanent and temporary) and a casual nursing pool of 2 nurses.

10. All nurses employed by CFMU are Clinical Nurse Consultants (CNCs) at the Nursing Grade 7 classification. They work to top of scope and are accountable for the advanced clinical practice and provision of clinical assessment, planning and treatment, based on critical analysis of symptoms and medical history as well as:

- Being accountable for outcomes and achievement of service performance targets;
- Being responsible for a specific portfolio and /or the completion of discrete projects;
- Being responsible for the implementation of clinical governance;
- Participating in quality initiatives and research to inform practice and practice change;
- Contributing to budget integrity and fiscal management; and
- Complying with professional standards, contemporary HR requirements, organisational principles, policy and procedure and legislative requirements.

Question 8 – Who is ultimately responsible for nurses conducting forensic medical examinations in in Queensland? If it is not you or the Clinical Forensic Medicine Unit (CFMU), clarify your role and the role of the CFMU with respect to such nurses.

11. Since July 2019, HHSs have been responsible for ensuring the delivery of essential, accessible, and sustainable sexual assault services in Queensland. A range of enabling instruments were developed and implemented to support the introduction of Caring for People Disclosing Sexual Assault Health Service Directive (Please see Exhibit JJT-2). Additionally, Queensland Health has, and continues to provide re-current funding to enable HHSs nurses and midwives to undertake training to provide sexual assault services (the targeted funding provides for backfill, associated travel costs and provision for nurses from remote HHSs). Furthermore, HHSs receive funding on a quarterly basis to cover recall costs for each sexual assault examination performed.



Jacqueline Jane Thomson Witness

12. I am responsible for the administration of the Sexual Assault Nurse Examiner Program including, but not limited to professional support, system support, education, research, and professional leadership.

13. Clinical Forensic Medicine Unit medical personnel revised the original SANE program, conduct quarterly SANE workshops, and provide clinical advice 24 hours a day, seven days a week.

Type of nurse examiners

Question 9 – Can any nurse employed or engaged by QH conduct a forensic medical examination of a sexual assault complainant or a person accused of sexual assault? If no, what type of nurses can conduct such examinations?

14. No. For a Queensland Nurse and/or Midwife to conduct a forensic examination they must have completed the relevant qualifications. In the case of a FNE (Forensic Nurse Examiner), a Graduate Certificate in Forensic Medicine or a Graduate Certificate in Medical and Forensic Management of Adult Sexual Assault is required. As a SANE, they are required to have completed an appropriate SANE academic course.

15. SANEs are not permitted to conduct a sexual assault examination on a person accused of sexual assault. A FNE is authorised to do so.

16. A SANE can provide a Statement of Fact but cannot offer opinion. FNEs can provide expert opinion.

17. For clinicians doing this work who do not have appropriate qualifications and expertise in the field, they should be working closely within a supportive multi-disciplinary team environment with appropriate clinical governance, ideally at an HHS level to ensure local service needs are met.

Question 10 – What is a forensic nurse examiner (FNE)? What qualifications and/or experience are necessary for a nurse to be a forensic nurse examiner? What are their responsibilities?

18. A Forensic Nurse Examiner is a nurse who is qualified to provide consultation and testimony for legal proceedings that are either civil or criminal in nature and relate to nursing practice, care given, and opinions rendered regarding findings such as injury interpretation.

19. A high proportion of Queensland FNEs were sponsored by the Department of Health to enrol in the Master of Forensic Medicine at Monash University, Melbourne, Australia. They exited the course with a Graduate Certificate of Forensic Medicine after the successful completion of 24 credit points. Monash University no longer offer this course to nurses. The course is now only available to medical, dental or radiographer professionals.

20. Nationwide, there are two institutions that offer post graduate forensic study.

21. The New South Wales Education Centre Against Violence (ECAV) has a Graduate Certificate in Medical and Forensic Management of Adult Sexual Assault. Please see Exhibit JJT-3.

22. The University of Notre Dame Australia offers a Master of Nursing with Forensic nursing as a specialisation. Please see Exhibit JJT-4.

23. The responsibilities of Forensic Nurse Examiners include examination and treatment of victims and alleged perpetrators in investigation of all crimes against the person, including sexual assault of adults. This includes gaining informed consent, forensic history taking, evidence collection, documentation, and interpretation of injuries.

Question 11 – Approximately how many forensic nurse examiners are there currently? Are they located in every Hospital and Health Service (HHS), and is there any HHS where they are particularly concentrated?

24. As of 17 September 2021, there were 23 Forensic Nurse Examiners in Queensland.

25. Darling Downs Hospital and Health Service have five FNEs, Sunshine Coast Hospital and Health Service have six FNEs and Townsville Hospital and Health Service have 4 FNEs.

Question 12 – Are forensic nurse examiners being currently recruited and/or trained?

a. If yes, at which institution(s) are they being trained, and how many are being recruited each year?

26. Two Metro North Hospital and Health Service SANEs have recently completed the ECAV Graduate Certificate in Medical and Forensic Management of Adult Sexual Assault.

b. If no, why not?

27. Queensland Health are working to achieve a quantum of SANEs to provide an essential and sustainable service as close to home as possible for victims/survivors of sexual assault, and who are interested in completing additional study in forensic nursing. A long-term goal is to work with a local tertiary partner to provide a FNE course in Queensland.

Question 13 – What is a sexual assault nurse examiner (SANE)? What qualifications and/or experience are necessary for a nurse to be a SANE? What are their responsibilities?

28. A SANE is a qualified, experienced nurse and/or midwife that has completed the necessary training and education to provide comprehensive medical forensic care to patients that present for services following a sexual assault.

29. For Queensland HHS nurses and midwives to be considered for the SANE course, the following elements must be satisfied:

- experienced nurses or midwives (minimum of 2 years of experience as a RN/RM);
- registered with the Australian Health Practitioner Regulation Agency;
- enrolment supported by the Hospital and Health Service Executive Director of Nursing and Midwifery (or equivalent); and
- agreeable to completing all course requirements and offering a return of service obligation by participating in an on-duty and/or on-call roster to conduct sexual assault examinations for a 12-month period.

30. Responsibilities of the SANE include:

- Providing emotional support;
- Assessing for mandatory reporting status and report when appropriate;
- Gaining informed consent;
- Ensuring medical clearance has been achieved where and when necessary;
- Assessing the patient's emotional state to determine if further evaluation or treatment is necessary;
- Documenting sexual assault medical forensic history taking and perform exam;
- Noting any areas of injury, including bruising, bite marks, and scratches;
- Obtaining swabs of the victim's oral cavity, cervix, rectum, vaginal or penile areas depending on information gleaned from the forensic history;
- Collecting urine samples where appropriate;
- Administering prophylactic medications and emergency contraception;
- Coordinating referrals for proper follow-up care as needed;
- Ensuring patient/medical record confidentiality at all times; and
- Testifying as a fact witness to cases performed.

Question 14 – Approximately how many SANEs are there currently? Are they located in every HHS, and is there any HHS where they are particularly concentrated?

31. As of 8 October 2022, **97** Queensland nurses and/or midwives have completed the full SANE program and can now participate in on-shift/on-call rosters to conduct sexual assault examinations. Please see Exhibit JJT-5.

32. SANEs are in the following HHSs:

HHS	Number of SANEs	Additional information
Cairns and Hinterland HHS	13	
Central Queensland HHS	16	

Central West HHS	1	
Darling Downs HHS	7	
Gold Coast HHS	2	Gold Coast HHS do not have SANEs as they have Forensic Physicians that perform sexual assault examinations at the Gold Coast University Hospital, Robina, and Logan Hospitals.
Mackay HHS	4	
Metro North HHS	10	
Metro South HHS	1	Victims/survivors requiring a sexual assault examination are referred to the Royal Brisbane and Women's Hospital.
North West HHS		North West HHS do not have SANEs, they have Medical Officers that perform sexual assault examinations.
Sunshine Coast HHS	2	Sunshine Coast HHS have few SANEs, as they have

		FNEs that perform sexual assault examinations at the Sunshine Coast University and Nambour Hospital.
South West HHS	2	Sexual assault examinations are conducted by Senior Medical Officers or the Director of Medical Services with support from the CFMU Forensic Physician on call.
Townsville HHS	7	
Wide Bay HHS	19	
West Moreton HHS	13	
Torres and Cape HHS	1 FNE	If a sexual assault examination is required. Option 1: Is to transfer the victim/survivor to tertiary facility (Cairns). Option 2: Where a SAIK or JIC SAIK is completed by a senior medical officer they seek clinical assistance and support

[redacted] [redacted]

Jacqueline Jane Thomson Witness

		from the CFMU Forensic Physician on call.

Source: CFMU SANE and FNE data and Sexual Assault Service Assessment

Question 15 – Currently, are SANEs being recruited and/or trained?

33. Yes.

a. If yes, at which institution(s) are they trained, and how many are being recruited each year?

34. HHSs determine how many SANEs they require to ensure that they have a sexual assault service that is accessible and sustainable. The recruitment is rolling (month on month) in nature. Dates of the SANE workshops are published at https://qheps.health.qld.gov.au/fss/forensic-services/response-to-sexual-assault/sexual-assault-nurse-examiner-course. This assists the senior responsible officer at the HHS level who support the SANEs, and SANE course enrolees to pace completion of modules appropriately to ensure that they are able to attend a workshop as close as possible to coursework completion.

35. The Queensland Health Sexual Assault Nurse Examiner program is hosted on the Central Queensland University Platform. Successful students are awarded a digital badge issued by CQ University in partnership with Queensland Health to validate their knowledge and skills with their employers and recognise their professional development and valuable contribution to improved service delivery across Queensland. Please see Exhibits JJT-6 and JJT-7.

b. If no, why not?

36. Not applicable

Question 16 – Identify and attach any policies, procedures, or guidelines relevant to your responses to the questions 9 to 15.

[redacted] [redacted]

Jacqueline Jane Thomson Witness

37. Please see Exhibits JJT-6 and JJT-7.

Particular topics related to nurse examiners

Question 17 – Do forensic nurse examiners and SANEs use the sexual assault investigation kit (SAIK) produced by QH Forensic and Scientific Services (FSS), or something else, when:

a. conducting a forensic medical examination on a sexual assault complainant; and

38. Yes. SANEs and FNEs use the SAIK produced by FSS. Where appropriate, additional swabs are collected and included in the kit.

b. conducting a forensic medical examination on a person accused of sexual assault.

39. FNEs use the SAIK produced by FSS when examining a person accused of a sexual assault. When required, additional swabs are collected and included in the kit.

40. SANEs **do not** conduct examinations on persons accused of a sexual assault.

Question 18 – Do forensic nurse examiners, SANEs and/or any other nurse conduct forensic medical examinations in relation to sexual assault matters on:

a. children aged 14 to 17 years; and

41. SANEs and FNEs conduct forensic medical examinations regarding sexual assault matters on children aged 14-17 years. Please see Exhibit JJT-8.

b. children aged under 14 years (if no, are there any plans to train nurses to be able to do so)?

42. No. Not that I am aware of, although access to a paediatric sexual assault examination by clinicians with appropriate qualifications and expertise in the field across a geographically challenged state is a known gap. Please see Exhibit JJT-9

Question 19 – Is there a preference between having a forensic nurse examiner conduct a forensic medical examination compared to a SANE, or is there no relevant difference?

43. There is no preference regarding provision of care for a victim/survivor of sexual assault. Perhaps the greatest difference is seniority, exposure, and experience. FNEs have been conducting forensic examinations since 2008, whereas SANEs have been available to conduct forensic examinations since 2020. FNEs can, but SANEs **cannot** conduct an examination on a person accused of committing a sexual assault.

Question 20 – Do you consider it to be preferable for a physician or a nurse to conduct a forensic medical examination of a sexual assault complainant, or is there no difference? Do you consider it to be preferable for a physician or nurse to conduct a forensic medical examination of a person accused of sexual assault, or is there no difference?

44. Victims/survivors of sexual assault must have access as close as possible to home to an essential service, such as a forensic examination, by clinicians with appropriate qualifications. Regarding preference of profession, a systematic review by Toon et al, 2014 noted that while there was no benefit gained in terms of prosecution and conviction between FMOs and FNEs, there was a significant statistical difference between provision of clinical care and provision of a fiscally responsive service.

45. Barriers to nurse led service need to be identified for HHSs that have been funded to provide Sexual Assault Nurse Examiners for the forensic examination of complainants of rape and sexual assault.

Question 21 – If, at a particular time, a hospital has available both a physician and a nurse who are each qualified to conduct a forensic medical examination of a complainant, is there any policy or procedure stipulating which should conduct the examination?

46. No.

Question 22 – In relation to the gender of the examiner:

a. **Do you know if sexual assault complainants who present to a hospital for a forensic medical examination are asked if they have a preference for the gender of the person who conducts the examination? If yes, identify any policy or procedure concerning such.**

47. No.

b. If, at a particular time, there are persons of both gender available to conduct a forensic medical examination on a sexual assault complainant (e.g. a female physician and a male nurse; or a female nurse and a male nurse), is there any policy or procedure which permits the complainant to request a physician/nurse of a particular gender?

48. No.

Question 23 – Are there any ongoing proficiency testing or continuing professional development obligations on nurses who conduct forensic medical examinations?

49. Yes. Hospital and Health Services determine the standards of clinical practice, minimum qualifications, scope of clinical practice, timeframes that credentials and defined scope of clinical practice is granted and limitations/conditions/rescinding of authorisations/performance management issues and issues impacting health. Please see Exhibit JJT-10.

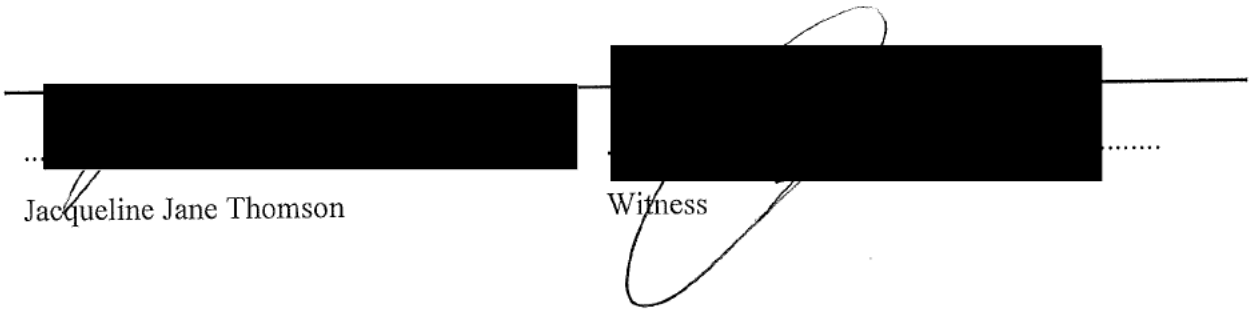
50. For a Hospital and Health Service that does not presently have a process for approval of nurses practicing as a SANE, a state-wide template has been co-designed with members of the Sexual Assault Nurse Examiner-Forensic Nurse Examiner Community of Practice (SANE-FNE CoP). This document received endorsement by members of the Statewide nursing and midwifery educator's forum on 10 October 2022. Please see Exhibit JJT-11.

51. **Question 24 – Identify and attach any policies, procedures or guidelines relevant to your responses to the questions 17 to 23.**

52. Please see Exhibit JJT-11.

<u>Other issues</u>

Question 25 – Do nurses who conduct forensic medical examinations on a complainant currently also take a reference DNA sample?



Jacqueline Jane Thomson

Witness

a. **If yes, attach any policy instructing them to do so, and identify the method by which they take a reference DNA sample.**

53. No. The current process is that QPS personnel collect the reference DNA sample on a complainant.

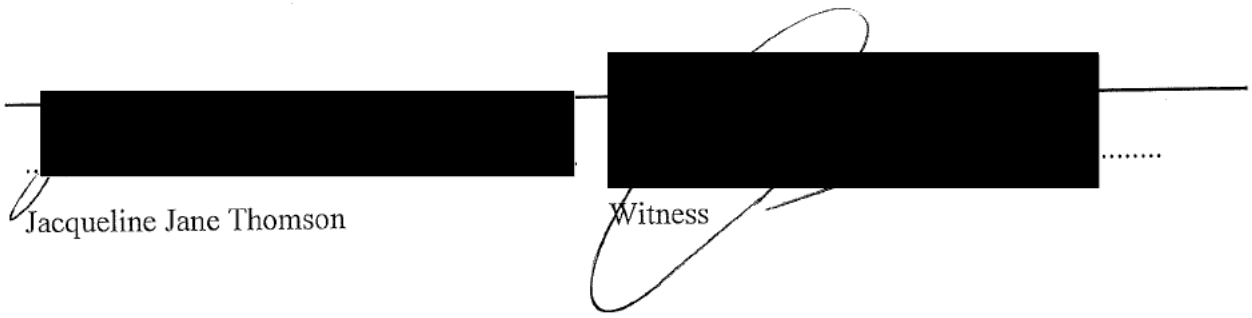
b. **If no, do you think nurses are able to competently collect reference DNA samples if required to do so? Advise if you see any problems with a nurse collecting reference samples when conducting the examination.**

54. Yes. I do not see any problems with a SANE/FNE collecting a reference sample when conducting the examination. Access to the necessary clinical consumables, education, training, and the development of supportive resources would be required. This is all very achievable. I understand that this action is completed nationally and internationally by SANEs.

Question 26 – Have any problems or concerns been identified or raised with you regarding the methods, systems or processes used by nurses in conducting forensic medical examinations? If yes, when, by who, how and what was the problem or concern? If no, confirm same.

55. Concerns have been raised from nurses/midwives with their senior responsible HHS officer upon completion of the SANE workshop regarding lack of readiness and confidence in conducting sexual assault examinations. While not mandated, where able, SANEs are buddying up with multidisciplinary colleagues that have received training in forensic examinations for their first couple of examinations before conducting examinations unsupervised.

Question 27 – Do you, SANEs, or forensic nurse examiners receive any communication or feedback from FSS or the Queensland Police Service about the SAIKs conducted and the quality of biological samples that are obtained from them – whether in particular cases or at a more systemic level?



Jacqueline Jane Thomson

Witness

56. Yes. On 31 August 2022 at 10:31 am, I received an email from the Team Leader – Evidence Recovery & Quality Team sharing issues identified by the Forensic Property point regarding SAIK non-conformance. (Please see Exhibit JJT-12). As an action I created an email that was distributed through the SANE-FNE Community of Practice drawing to members' attention a Situation, Background, Assessment Recommendation document regarding the packaging of swabs, and other biological specimens collected in a JIC/QPS SAIK. I asked that colleagues re-visit the document and ensure that practice conforms with the process for packaging. (Please see Exhibit JJT-13).

a. **Would you be assisted by the provision of such feedback, or similar consultation? Why/why not?**

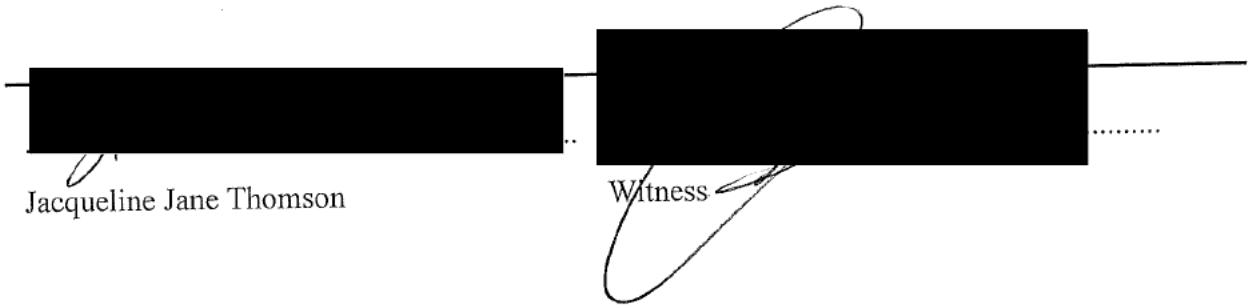
57. See above.

Question 28 – Identify and detail any other concerns, criticisms, or feedback you have of the current Queensland SAIK model and the current processes for collecting biological material for forensic DNA testing by nurses. Would you like to see any changes? Would the quality of forensic services be improved if your unit had greater visibility or a greater role across the state? Attach supporting documents if necessary.

58. The efficiency and effectiveness of centralised state-wide support and training for frontline clinical forensic services is questionable. An option is to ensure that HHSs are funded to set up integrated hospital forensic service hubs – staffed with forensically qualified Faculty of Clinical Forensic Medicine, The Royal College of Pathologists of Australia doctors, with forensically trained ED doctors and nurses that are funded separately to do the work.

59. For regional rural and remote facilities there is real opportunity for HHSs to trial using telehealth technology who present for services following a sexual assault.

60. Inability to grow the SANE program to include the monitoring and evaluation + feedback loop of sexual assault services in Queensland Hospital and Health Services, as there are no KPIs built into the Service Level Agreement with Queensland Hospital and Health Services (HHSs).



Jacqueline Jane Thomson

CURRICULUM VITAE

Jacqueline Jane Thomson

[redacted]

Profile

With over 34 years of healthcare experience and the completion of post-graduate study, I bring to the work environment an expert and comprehensive knowledge of:

- Contemporary nursing and midwifery practice
- Effective leadership and management skills
- Advanced clinical skills
- Demonstrated expertise in business acumen, policy development and project management
- Excellence in communication skills (written and verbal) and the ability to inspire and mentor a team and individuals.

My ability to engage and work collaboratively with stakeholders (internal and external) and work successfully with lines of authority, ensures that I achieve results that are timely, tangible, and sustainable.

My career has consistently focused on establishing goals and strategy that influences quality and safety clinical outcomes, processes, and performance. I am continually in pursuit of positive results. With expertise in strategic and operational planning, change management and stakeholder engagement, as well as, my personal commitment, energy, drive and integrity; I have achieved many successes in the development, implementation and evaluation of major legislative reform, statewide programs of work and projects regarding the improvement in the delivery of healthcare services.

Summary of qualifications

2022	Master of Business Administration candidate	Griffith University, Queensland
2021	Introduction to the medical and forensic management of adult sexual assault	NSW Government, Education Centre Against Violence
2016	Breakthrough Series College Graduate	Institute for Healthcare Improvement
2015	Graduate Certificate in Policy Analysis	Griffith University, Queensland
2014	Lean Six Sigma Green Belt Certification	Department of Health, Queensland
2008	PM Plus Essentials	Department of Health, Queensland
2004	Certificate in Sexual and Reproductive Health Theory	Family Planning Queensland
1996	Bachelor of Nursing (Post-Registration	Queensland University of Technology
1994	Midwifery Certificate	Royal Women's Hospital, Queensland
1991	General Nursing Certificate	Royal Brisbane Hospital, Queensland

AHPRA Registration No: NMWOOO1439881	Registered Midwife (Qld)
AHPRA Registration No: NMWOOO1439882	Registered Nurse (Qld)

Employment history

March 2020 – Current

Assistant Director of Nursing (NG10.2)
Clinical Forensic Medicine Unit (CFMU)
Forensic and Scientific Services

In this role I have:

- Provide high level contemporary, strategic, operational, and professional nursing leadership and management to Clinical Forensic Medicine Unit nursing personnel that provide healthcare at the Brisbane City Watchhouse.
- Work collaboratively with internal and external stakeholders to shape corporate and clinical governance within the Brisbane City Watchhouse.
- Developed a phased model of care that offers quality and safe healthcare to detainees, improves the use of finite human resources, satisfies partner requirements, offers sustainability, succession planning and improved the saving level of the unit by being fiscally responsible.
- Completed the Business Planning Framework and service profile for the CFMU nursing service.
- Responsible for the administration of the Sexual Assault Nurse Examiner Program including, but not limited to professional support, system support, education, research, and professional leadership.
- Collaborated with the Queensland Police Service to establish the Brisbane Watchhouse Clinical Governance Partnership. The purpose of this partnership is to provide high level, strategic leadership and systemic advice that will improve the health and well-being of persons detained in the Brisbane Watchhouse.
- Created the Sexual Assault Nurse Examiner and Forensic Nurse Examiner Community of Practice and assumed a lead role in facilitating initiatives and outcomes to support professional, clinical, and organisational imperatives for Hospital and Health Service Sexual Assault Services.
- Provided specialist sexual assault policy advice to the Minister, the Director-General, Deputy Director General, senior departmental executives, and stakeholders that may have significant political, community and business impacts.
- Sourced business intelligence (data/analytics) to substantiate performance.
- Supported colleagues to advance themselves, as well as, addressing underperformance swiftly and consistent with procedural fairness principles.
- Recruited to vacant nursing positions.
- Participated in the development of the unit COVID-19 pandemic plan.

January 2019 – March 2020

Manager, A08
Healthcare Improvement Unit
Clinical Excellence Queensland
Department of Health

At the request of the Deputy Director-General (DD-G), now the Director General, Queensland Health, I was asked to progress tranche two of the termination of pregnancy program of work. This entailed me working with Hospital and Health Services (HHSs), as well as industry bodies, peak agencies, and private health providers in the sector to ensure that:

- Suitable arrangements are in place that enable Queensland women to have access to high quality, safe and timely termination of pregnancy services.
- Public/private partnership developments are where appropriate, supported and promoted.
- Service agreements are established, monitored and reports received/actioned as appropriate.
- Specialist policy advice is provided to the Minister, the Director-General, Deputy Director General, senior departmental executives, other jurisdictions, and stakeholders on clinical issues that may have significant political, community and business impacts.
- Risks relating to the implementation of government policy on termination of pregnancy are appropriately managed.
- Communication and consultation within the ecosystem is established and maintained.

August 2018 – January 2019 Manager, A08
Office of the Deputy Director-General
Clinical Excellence Queensland
Department of Health

At the request of the DD-G, CEQ, in this role I:

- Led the complex policy work that informed the *Termination of Pregnancy Act 2018*.
- Managed the full project lifecycle to achieve implementation of the Queensland Termination of Pregnancy Act 2018 on time, within budget and to the agreed quality specifications.
- Established the Queensland Legislative Reform for Termination of Pregnancy Steering Committee to bring identified key stakeholders together to undertake project governance, formulation, and oversight, as well as assist with the coordination and implementation of the Queensland termination of pregnancy legislation.
- Prepared a range of written materials including executive correspondence, briefing material, project documentation, contract agreements and information papers concerned with the initiatives and deliverables of the project.

October 2016 – August 2018 Manager, A08
Healthcare Improvement Unit
Clinical Excellence Queensland
Department of Health

In this role I have:

- Administered the New Technology Funding Evaluation Program, Integrated Care Innovation Fund and provided oversight for the evaluation of models of care.
- Managed and coordinated the human and financial resources of the Healthcare Evaluation and Assessment of Technology (HEAT) team to ensure that business outcomes, project deliverables and deadlines are achieved.
- Provided specialist policy advice to the Minister, the Director-General, Deputy Director General, senior departmental executives, other jurisdictions, and stakeholders on technology issues that may have significant political, community and business impacts.
- Represented Queensland on the Health Technology Reference Group and the Nationally Funded Centre's Committee.

- Consulted and negotiated with internal and external clients, industry groups, and other government agencies (federal, state, and local), the public and other stakeholders.
- Wrote and/or reviewed complex reports, briefing notes, departmental and other correspondence in accordance with departmental standards.
- Actively managed staff development and performance for HEAT team members.
- Promoted and ensured compliance of work with public sector legislation, standards, policies, practices, and procedures relating to human, financial and physical resources.

March 2015 – October 2016 | Director of Nursing and Midwifery, NRG 10.4 & NRG 12
Office of the Chief Nursing and Midwifery Office
Office of the Director-General
Department of Health

In this role, I have:

- Project managed the complex policy work that informed legislating minimum nurse-to-patient ratios in the state's public-sector healthcare facilities.
- Co-led the investigation into processes and procedures as a means to improving patient safety in healthcare by a Hospital and Health Service in South-East Queensland.
- Provided professional and strategic leadership for key policy commitments of the Queensland Government related to Nursing and Midwifery.
- Influenced the removal of legislative barriers to midwifery scope of practice. For example, provided advice on the proposed changes to the DTP for Queensland midwives in the Health (Drugs and Poisons) Regulation 1996.
- Identified information from a wide range of sources including Professional Nursing and Midwifery Colleges and provided strategic analysis and advice on complex operation program, policy, and legislative issues.
- Established the Midwifery and Maternity Services Reference Group to bring consumers and leaders in the field of midwifery together to discuss and determine what actions are required to drive safe, high quality and sustainable midwifery and maternity services across Queensland.
- Provided professional advice to the Queensland Minister for Health and Minister for Ambulance Services regarding the development of midwifery services in Queensland.
- Prepared a range of written materials including two cabinet submissions, executive correspondence, briefing material, project documentation and information papers concerned with the initiatives and deliverables within the portfolio.

September 2013 – March 2015 Principal Project Officer, A07/4
Clinical Access and Redesign Unit
Health Systems Innovation Branch
Health Services and Clinical Innovation Division
Department of Health

The purpose of this position is to establish, implement and evaluate the Strategies to Improve Gastrointestinal Endoscopy Access in Queensland 2013-2015.

In this role, I was required to:

- Provide high level program management advice and direction in relation to the project initiatives.
- Identify information from a wide range of sources and provide strategic analysis and advice on complex operation program, policy, and legislative issues.
- Coordinate the day-to-day operations to deliver on project outcomes that support the Departments capacity to deliver and maintain quality gastrointestinal services.
- Provide high level liaison, consultation, and negotiation with internal and external stakeholders to achieve the program initiatives.
- Work closely with and support Hospital and Health Service colleagues and non-government healthcare providers to systematically improve the outcomes for clients and reduce the variability of service quality by contributing to the development of systems and processes (develop, monitor, and review policies, procedures, and business rules) that promote clinical governance.
- Prepare a range of written materials including executive correspondence, briefing material, speech notes, project documentation and information papers concerned with the program's initiatives and deliverables.

August 2010 – September 2013 Principal Project Officer, A07/4
Patient Safety Quality Improvement Service
Centre for Healthcare Improvement
Department of Health

Employed in a full-time capacity I planned, organised, coordinated, and supported the Statewide Maternity and Neonatal Clinical and Diabetes Network Clinical Chairs and Steering Committees to achieve their priority strategic and operational initiatives.

Principal responsibilities of this role:

- Provided authoritative strategic support and advice promoting state-wide evidence based, client-centered, value driven maternity, neonatal and diabetes care consistent with the Queensland Health Strategy.
- Accountable for the fiscal management and reporting of the networks funding.
- Identified and developed clinical practice improvement indicators using quality improvement methodologies.
- Organised bi-annual forums conducting workshop sessions to identify priority initiatives going forward.

- Organised and provided secretariat support for steering committee and work group meetings.
- Established and supported work groups using project management methodologies to achieve deliverables in scope, on time and within budget.
- Identified marketing opportunities to advance the profile of the clinical networks and working groups.
- Established and supported network systems.
- Developed and managed collaborative partnerships with identified key stakeholders to facilitate improved service responsiveness.
- Prepared submissions, briefings, and other complex reports.

June 2008 – August 2010 Principal Project Officer, A07/4
Maternity Unit
Primary, Community & Extended Care Branch
Policy, Strategy and Resourcing Division
Department of Health

In this role, I provided advice on policy and strategic leadership on clinical service issues and strategies to facilitate and support change management process relevant to maternity care, post-natal contact services and the rural maternity initiative consistent with current Queensland Health policies and program directions.

Principal responsibilities of this role:

- Provided leadership in the development of best practice maternity models of care, promoting the use of contemporary evidence-based approaches, implemented risk mitigating strategies and assisted in the development of policy, guidelines, pathways, and process.
- Investigation into processes and procedures as a means to improving patient safety in healthcare delivered by a maternity service – Tasked with examining current practices and processes and identifying areas for improvement.
- Led the development of system, processes, protocols, and guidelines to ensure the sustainability of policy directions for maternity services.
- Developed collaborative partnerships with key internal and external stakeholders to facilitate improved service responsiveness.
- Provided proactive high-level advice to senior management on clinical resource, health system reform and workforce development implications related to Queensland Health maternity services.
- Provided leadership in the development, implementation and evaluation of Queensland Government initiatives, strategies, and programs to support and implement policies and directions for maternity services.
- Prepared a cabinet submission, briefings, complex reports, and other written material.

March 2005 – June 2008 Nurse Unit Manager, NO7/4
Women's and Children's Unit, Kingaroy Hospital
West Moreton South Burnett Health Service District

As the Nurse Unit Manager for Kingaroy Medical Ward, Surgical Ward and Maternity Services. I was responsible for the leadership and management of a 42-bed unit with service deliveries that encompassed two high dependency monitored beds, diverse clinical modalities not restricted to medical, surgical, paediatrics, antenatal, postnatal, 2 bed birthsuite, nursery with CPAP and ventilatory capabilities, antenatal clinics twice a week, as well as ante-natal classes three days/month.

The unit had more than 400 births/year and conducted theatre on average three days/week. Direct nursing FTE reports was 24 which consisted of FT/PPT CN's/RN's/RM's, EEN's/casual staff and agency staff, as well as one non-nursing FTE (ward clerk).

Principal responsibilities of this role:

- Responsible for the cost centre and human resource management for the unit inclusive of:
    - Running roster validation reports, to check roster effectiveness post inclusion in Workbrain.
    - Checking for fatigue and overtime.
    - Printing daily staffing variance forms to identify and record changes for submission to Payroll Services the following business day.
    - Viewing employee and leave information as required.
    - Recording staff skills and completion of key training courses relevant for HHS accreditations.
- Provided advanced evidence based clinical care to high and low risk pregnant and non-pregnant women, neonates, paediatric, gynaecological, medical, and surgical clientele.
- Managed complaints and compliments.
- Completed the self-assessment report against all ACHS EQuIP mandatory clinical criteria, creating evidence folders, preparation and presence for on-site survey and ensuring the outcomes were achieved for identified key improvements.
- Managed clinical products including but not limited to product trials; evaluations; impress and clinical consumables.
- Managed service agreements.
- Supported clinical governance policy and framework within my area of responsibility.
- Influenced quality improvement and patient safety management at the strategic, operational and individual level.
- Explored and developed partnership models and strategies to support undergraduate and postgraduate nurses within the unit.
- Prepared articles for publication in the Health Service District newsletter and local print media as well as District representative on local radio.
- Provided after hours on call as the Executive representative as senior nursing resource officer for the hospital.

Queensland Health

Caring for people disclosing sexual assault

Directive number: QH-HSD-051:2019

Effective date: 22 July 2019

Review date: 22 July 2022

Supersedes: New

On this page:

- Purpose
- Scope
- Principles
- Outcomes
- Mandatory requirements
- Related or governing legislation, policy and agreements

- Definitions of terms used in this directive
- Version control

Purpose

This Health Service Directive requires Hospital and Health Services to take a consistent approach to managing the clinical and psychosocial needs of people who have experienced sexual assault. This includes the person-centred provision of forensic examinations.

Scope

This directive applies to all Hospital and Health Services (HHSs).

Principles

- Compassion—everyone disclosing sexual assault will be treated with respect, courtesy, compassion and dignity and their clinical care and any forensic examination will be responsive to their particular needs including access to, or referral to counsellors and support services.
- Person-centred care—everyone disclosing sexual assault will have access to trained clinicians who can provide timely and confidential clinical care and forensic examinations after presentation to hospital.
- Information—everyone disclosing sexual will be given clear information about their options relating to having a forensic examination and the level of involvement of police.
- Collaboration—HHSs will work effectively with the Queensland Police Service, other government agencies as well as community organisations to ensure a responsive, supportive and integrated approach to caring for people disclosing sexual assault.

Outcomes

Hospital and Health Services included in the scope of this directive shall achieve the following outcomes:

- Compliance with Queensland Government Interagency Guidelines for Responding to People Who Have Experienced Sexual Assault.
- Compliance with the Queensland Health Guideline: Guideline for management of care of people 14 years and over disclosing sexual assault
- Compliance with the Department of Health Guideline: Conducting Child Sexual Assault Examinations (*Document Number # QH-GDL-943:2015*)
- Compliance with the informed consent requirements detailed in the Queensland Health Guide to Informed Decision-Making in Healthcare
- In doing so, HHSs will provide consistently high-quality, compassionate and person-centred services to people disclosing sexual assault who present to public hospitals.

Mandatory requirements

Hospital and Health Services (HHS) will:

- Provide 24-hour access to clinical care and forensic examinations for people 14 years and over disclosing a sexual assault in accordance with the Guideline for the management of care of people 14 years and over disclosing sexual assault.
- Ensure everyone who discloses that they are the victim of a sexual assault is informed of their choices about forensic examinations and reporting the assault to police, including the benefits of early reporting.
- Provide forensic examinations to victims of sexual assault when victims choose to have a forensic examination regardless of whether victims decide to report the matter to police or decide to defer this decision.
- Ensure adherence to informed consent for all aspects of caring for people disclosing sexual assault, including clinical treatment, forensic examinations, evidence collection and storage, police involvement, referrals and the release of information to third parties.
- Provide clear information about the storage, access and destruction of forensic examination samples to victims of sexual assault who have a forensic examination but choose to defer the decision to report the assault to police.
- Provide a suitable model of care for managing paediatric sexual assault patients (under 14 years of age) within each HHS.
- Report all suspected child sexual assaults to Child Safety Services in line with the mandatory reporting and duty of care responsibilities of clinicians.
- Ensure all patients are referred to (with patient consent) and/or provided information regarding sexual assault counselling and support services.

Director-General
Queensland Health

Approval date: 17/07/2019

Issued under section 47 of the *Hospital and Health Boards Act 2011*.

Definitions of terms used in this directive

Term	Definition / explanation / details	Source
Hospital and Health Service	Hospital and Health Services are statutory bodies and are the principal providers of public sector health services.	*Hospital and Health Boards Act 2011*
Forensic Examination	The forensic examination consists of obtaining a history as to the nature of the assault to guide the subsequent physical examination. It also includes interpretation of injuries and the collection of forensic samples as it relates to the alleged sexual assault. (A Sexual Assault Investigation Kit (SAIK) is used to collect DNA evidence)	Queensland Government Interagency Guidelines for Responding to People Who Have Experienced Sexual Assault.
Child	Under the age of 18 years For child victims of sexual assault, under the age of 14 years, sexual assault medical and forensic examinations should be performed by a medical officer with appropriate paediatric skills including child protection and/or sexual assault medical examination training or skills.	Department of Health Guideline: Conducting Child Sexual Assault Examinations (Document Number # QH-GDL-943:2015)
Trained Clinicians	Forensic Examinations can be provided by: • Forensic Physician • Medical Officers who have received training in sexual assault examination • Senior Medical Officers accessing phone support from Clinical Forensic Medicine Unit • Government Medical Officers • Forensic Nurse Examiners (postgraduate qualification in Forensic Medicine)	

- Sexual Assault Nurse Examiners. Nurses trained in sexual assault examinations having completed a recognised short-course eg SANE 40CPD short course)

Education Centre AGAINST VIOLENCE

NSW GOVERNMENT Health

Course Information Flyer 2023

NATIONALLY RECOGNISED

10724NAT Graduate Certificate in Medical & Forensic Management of Adult Sexual Assault

Course Number:	Location:	Coordinator:	Applications Close:
MF 1401	NSW	Sonali Panda	05 May 2023

Target Group:

- Doctors working for NSW health who are required to provide medical care and forensic examinations to adult victims of sexual assault
- Registered nurses who are training to become Sexual Assault Nurse Examiners working for NSW health who provide medical care and forensic examinations for adult victims of sexual assault.

Description: This course adheres to the Australian Qualifications Framework (AQF) and has been accredited by the Australian Skills Qualification Authority (ASQA). It is delivered by Education Centre Against Violence (ECAV) delivery partner of NSW Health RTO (code 90198). This course delivers skills based training that aims to provide graduates with the skills and knowledge to provide medical and forensic care to adult victims of sexual assault in health settings. The course has been developed specifically to meet the needs of rural practitioners.

Clinicians who complete this course may be employed in positions such as forensic nurse examiner; sexual assault nurse examiner; forensic medical examiner; medical officer sexual assault service.

Assessment tasks will include: written assignments, case portfolio, an objective structured clinical evaluation, and moot court evaluation and multiple choice questions.

This is a blended learning program. The majority of the teaching and learning occurs online via webinars and interactive modules. However, there are two compulsory three day face to face workshops held in Sydney for Sydney cohort and in Tasmania for the Tasmania cohort.

Learning Outcomes:

- Communicate effectively with diverse patients, within a specific legal framework
- Respond to the immediate and ongoing health needs of an adult male or female patient following a sexual assault
- Perform a forensic medical examination and specimen collection and document the findings and procedures
- Recognise injury types and describe the forces that produce injuries
- Fulfil your obligations to provide expert evidence to the criminal justice system within the boundaries of your expertise

Course structure

There are a total of 7 units

Units	Code	Competency Unit Title
Units of Competency	MFMASA001	Work effectively within an adult sexual assault context
	MFMTIA002	Implement a trauma informed approach to medical and forensic care
	MFMMFC003	Provide adult sexual assault medical and forensic care
	PUALAW003	Give evidence in a judicial or quasi-judicial setting
	MFMMDP004	Implement and support multidisciplinary practice
	CHCLEG001	Work legally and ethically
	MFMCSP005	Deliver culturally safe and respectful patient care to Aboriginal people

Semester Duration	Subjects	Dates
Semester 1 (July 2023 to October 2023)	Introductory Course and online learning Face to Face teaching (Lecture day, Moot court and Simulation workshop)	Introductory Course 31/07/2023 – 31/10/2023 **Sydney** Face to Face Workshop Dates 12/10/2023 – 14/10/2023
Semester 2 (February 2024 to June 2024)	Legal curriculum (online learning) Practice court sessions (virtual classrooms) Face to face workshop (Aboriginal cultural competency workshop, OSCE and moot court)	February 2023 **Sydney** Face to Face Workshop Dates 16/05/2024 – 18/05/2024

Course Costs:
You are responsible for funding your travel, accommodation and course fees. Should you experience any difficulty please discuss it with the Course Coordinator.

Costs:
NSW GPs – Free

NSW SANEs – Free

Pre-requisites:
To gain entry to this qualification, candidates must meet the following conditions:

Be a qualified, registered medical practitioner with a minimum of 2 years full time equivalent post graduate experience. They should be working in a field where proficiency in the assessment of common gynaecological conditions is required. Examples include(but are not limited to) General Practice, Sexual Health, Family Planning, Obstetrics & Gynaecology & Emergency Medicine
OR
Be a qualified nurse with a minimum of 3 years clinical experience or a qualified nurse practitioner. They should be working in a field where proficiency in the assessment of common gynaecological conditions is required. Examples include (but are not limited to) Sexual Health, Family Planning, Women's Health, Obstetrics & Gynaecology & Emergency Medicine.
AND
Be working in or observing at a clinical service providing medical and forensic care to people experiencing sexual assault.

All candidates will be interviewed for suitability for the course. The interview process will involve filling out a set of interview questionnaire and a telephone conversation with the Program Coordinator, Dr Eleanor Freedman.

Enquiries and Application/Expression of Interest:

Please complete the expression of interest on the ECAV website:

The course coordinator will be in contact to discuss your expression of interest in attending the course.

THE UNIVERSITY OF NOTRE DAME AUSTRALIA

Master of Nursing (Forensic Nursing)

School of Nursing & Midwifery, Fremantle Campus

The Master of Nursing (Forensic Nursing) from The University of Notre Dame Australia is a qualification designed for you if you have already completed a Graduate Diploma of Forensic Nursing. The program is run over the course of two semesters, and you will choose an area of research relevant to your specialist nursing practice.

Why study this degree?

If you want to extend your formal qualifications as a Registered Nurse, the Master of Nursing (Forensic Nursing) allows you to develop your specialist knowledge in this particular area of healthcare and operate at an advanced level.

Our Master of Nursing (Forensic Nursing) can be completed across two semesters of part-time study and you should have already completed a Graduate Diploma of Forensic Nursing at Notre Dame. You will generally choose a thesis

subject relevant to your specialist area of nursing practice, so we recommend discussing your study program with your postgraduate coordinator in advance.

Program summary

You will choose a research area relevant to their specialty of nursing practice.

Full details of the program requirements are contained in the Program Regulations (https://www.notredame.edu.au/__data/assets/pdf_file/0018/423 of-Nursing-Coursework.pdf).

Entry requirements

The program is open to Registered Nurses who have a previous degree, or to those who do not have a degree but who have accumulated a wealth of experience in nursing.

English Language Requirements

You must be able to demonstrate two years of full-time secondary, vocational or tertiary level of study in Australia, Canada, New Zealand, Republic of Ireland, South Africa, United Kingdom or the United States of America. If you do not meet these requirements you will need to sit the Academic IELTS exam and achieve a score of at least 7.0 overall and 7.0 in each sub-section (reading, writing, listening and speaking) to qualify for entry into the Master of Nursing (Forensics). This applies to Permanent Residents and Australian citizens whose first language is not English and have not completed two years full-time academic study in Australia. IELTS results will need to be verified by the Admissions Office before an offer of a place can be made. The Admissions Office reserves the right to

ask for IELTS results from any applicant. For more information, please visit www.ielts.org (https://www.ielts.org/)

Fees and costs

More information can be found at the Fees (https://www.notredame.edu.au/study/fees) page.

More information

For more information on the Master of Nursing (Forensic Nursing), please call our Prospective Students Office on [redacted]

Queensland Health Guideline

Document Number: QH-GDL-472:2019

Guideline for the Management of care for people 14 years and over disclosing Sexual Assault

1. Purpose

This guideline provides recommendations regarding best practice to support the management of people 14 years and over who have disclosed Sexual Assault. The guideline recognises that services can be adapted as appropriate to suit local capabilities.

2. Scope

This Guideline applies to all Hospital and Health Services (HHSs).

3. Aboriginal and Torres Strait Islander considerations

Hospital and Health Services should give consideration to providing cultural and gender appropriate services, including practitioners if possible.

4. Related documents

Queensland Government

5. Guideline for the management for people 14 years and over disclosing sexual assault

5.1. Principles

Hospital and Health services will have systems in place to offer adults disclosing that they are the victim of a sexual assault with medical care, psychosocial support and if required, access to a forensic examination. It is recognised that there will be local variation in how this is achieved but processes will:

- Maintain the patient's safety, confidentiality and privacy.
- Minimise further impact on a traumatised person by involving the minimum number of personnel possible in the clinical care and forensic examination and where possible offering choice of gender.
- Include support from social workers, sexual assault workers, nursing staff or relevant local non-government support services. Offer interpreter services where required.
- Recognise that investigation of sexual assault, a criminal offence, is a police matter. Patients will be encouraged to report the assault to police. However, where a patient with the capacity to consent is clear that they do not want police involved, they may choose to have a forensic examination. This may include a child aged 14 – 17 years of age who has parental consent for the examination and/or a Gillick-competent[1] child.
- Report all reasonable suspicions of child abuse and neglect in line with the mandatory reporting and duty of care responsibilities of clinicians.
- Commence within two hours of the patient's arrival in the Emergency Department and where possible by a minimum number of clinicians.
- Be based on informed consent for all aspects of the management including treatment and forensic examination. Adhere to defined meanings of consent, accounting for a person's capacity to consent, including that such capacity may require assessment if the adult person has a mental health disability, intellectual impairment or is temporarily affected by substances including alcohol.
- Recognise that a forensic examination is defined as a 'personal matter', in Part 2 of Schedule 2 of the Powers of Attorney Act, that is, not a health care matter.
- Ensure that consent for forensic examination for a person with impaired capacity can only be provided by an authorised power of attorney, (general power of attorney or Enduring power of attorney), appointed Guardian or the Public Guardian. Substituted decision-making by a statutory health attorney is not authorised for forensic examinations.
- Ensure that patients are aware that they may withdraw consent at any time.
- Ensure patients understand what happens to any samples from a forensic examination, including storage, access and destruction processes.

[1] A Gillick-competent child is one who has the capacity to consent despite being under 18 years of age. To be Gillick-competent, the child must have sufficient understanding, intelligence and maturity to appreciate the nature of the care to be provided, the consequences and risks, and the alternatives. This will vary according to the significance of the decision and factors within the child such as their maturity: Gillick v West Norfolk and Wisbech Area Health Authority [1986] 1 AC 112.

5.2. Clinical Care

1. **Nursing triage** on presentation at Emergency Department is as per all presentations including assessment for injuries and vital signs. Clinical interventions will take priority over forensic examination (*See Attachment 1*).
2. Immediately notify the Senior Medical Officer for any significantly injured or potentially unstable patients to arrange **urgent medical assessment**.
3. Offer all patients psychosocial support in a private environment, if available, and discussion of options including information to inform a decision on police involvement and a forensic examination.
4. For patients under 18 years, if a reportable suspicion[2] has been formed about a child, the treating health professional is to report that to Child Safety Services in line with mandatory reporting responsibilities of clinicians.
5. Pending consent of the patient and explanation of options, clinical staff trained in providing Sexual Assault examinations collect evidence using Sexual Assault Investigation Kit. See details in 7.3.
6. Accurate and comprehensive clinical notes should be recorded in the patient's hospital record. All clinical documentation should be made in accordance with QH-POL-280:2014 Clinical Records Management Policy as well as clinical documentation guidelines that are relevant to individual Hospital and Health Services. A forensic examination should be documented using an appropriate proforma. The forensic record is separate to the patient's clinical record. Copies of clinical documentation should only be filed in the forensic record if relevant to the forensic medical examination.
7. It is recommended that all examinations occur in the presence of an appropriate person acting as a chaperone / support person where possible.

5.3. Clinical Interventions

5.3.1. Time-critical interventions include:

- injuries sustained during the assault
- emergency contraception
- Hepatitis B vaccination +/- immunoglobulin
- HIV Post Exposure Prophylaxis (PEP)
- Chlamydia prophylaxis treatment.

5.3.2. Investigations include:

- for injuries as clinically indicated
- Beta-HCG if possibility of pregnancy pre-existing
- Full Blood Count (FBC), Electrolytes and Liver Function Tests (ELFTs) if commencing PEP
- other serology may be deferred until follow-up
- Sexually Transmitted Infection (STI) screening is recommended two weeks post episode by a relevant practitioner—this may be by referral to a general practitioner or sexual health service.

5.3.3. Clinical interventions (details in Attachment 2):

- Treat any injuries identified on assessment as clinically indicated.
- Consider Hepatitis B immunity.

---

[2] 'Reportable suspicion' about a child is defined in section 13E(2) of the Child Protection Act 1999 (Qld) as a reasonable suspicion that the child has suffered, is suffering, or is at unacceptable risk of suffering, significant harm caused by physical or sexual abuse; and, may not have a parent able and willing to protect the child from the harm. If a reportable suspicion has been formed, a written report must be given to the chief executive (section 13E(3)).

- Consider HIV risk: if high or uncertain risk HIV exposure, contact Infectious Disease physician or sexual health clinic for advice regarding PEP and follow up.
- Consider Emergency Contraception: Postinor 1 (levonorgestrel 1.5mg) up to 72 hours after reported assault or if >72hrs -120 hours, consider Ulipristal acetate.
- Consider STI prophylaxis if unreliable follow up or patient concern.
- Consider Tetanus Prophylaxis if indicated.
- Arrange appropriate follow up: this follow up will vary with site, reported events, individual circumstances and background medical issues.

5.4. Psychosocial Interventions:

Where available, the person should be referred to a Sexual Assault support service or Social Work service for post-acute support such as:

- assisting to the person to return to their usual level of functioning
- providing information about options available including their rights as a victim of crime.
- practical support, including contacting family members or support persons. If consent provided, talk to family members or support persons about how best to support the patient
- advice on 'common' responses, symptoms and reactions following a sexual assault
- psychosocial and risk assessment – physical, psychological and/or financial risk to patient and any noted child protection concerns
- information and referral, with consent, to relevant sexual assault support service.

The social worker, or other health professional, should also advise the patient of their right to:

- sexual health medical advice, treatment and follow up
- information about reporting options, including making a formal complaint to the Queensland Police Service
- referral to the Queensland Police Service via PoliceLink on telephone 131 444 to report the matter or attend any police station in their area to discuss their legal options
- Queensland Police Service's alternate reporting options
- referral to the state-wide Sexual Assault Helpline on telephone 1800 010 120.

For those under 18 years, report all suspected sexual assaults in line with mandatory reporting responsibilities of clinicians.

Where the sexual assault has occurred within an intimate personal relationship, family relationship or an informal care relationship, the patient should be informed of their option to seek protection under the Domestic and Family Violence Protection Act 2012. Where appropriate, the patient should also be referred to a specialist domestic violence service for support and assistance.

5.5. Forensic Examinations:

- Wherever possible, the forensic examination should be provided by a suitably trained clinician such as a Forensic Nurse Examiner; Nurse(s) trained in sexual assault examination; Government Medical Officer(s); Forensic Physician; or other Medical Officer(s) who have received training in forensic examinations.
- When there is no trained clinician available, a Senior Medical Officer can complete the examination accessing phone support from the Clinical Forensic Medicine Unit.
- A sexual assault investigation kit (SAIK) should be used, and a sexual assault examination record completed.
- Care should be taken to minimise the risk of DNA contamination from the room's fixtures and facilities.

- If the patient consents to a forensic examination but does not wish to make a formal complaint to police or wishes to defer this decision, then the examination is performed without notification to police. In this case, Queensland Health stores the sample centrally until such a time that the patient decides to report the sexual assault to police, or the sample is destroyed after 12 months. Patients should provide written acknowledgement that the sample will be destroyed after 12 months, unless QPS request the sample following a complaint to QPS by the patient.
- Release of patient information and specimens to police should only occur with the patient's consent.
- Examiners should ensure that chain of custody obligations are rigorously attended to, ensuring that the validity of collected forensic evidence is maintained.
- Forensic examiners with scope of practice in Adult sexual assault must NOT perform forensic examination for patients under the age of 14 years. Forensic examiners with a scope of practice in paediatric sexual assault may attend all patients 18 years and under.

6. Definition of Terms used in the guideline

Term	Definition / Explanation / Details	Source
Hospital and Health Service	Hospital and Health Services are statutory bodies and are the principal providers of public sector health services.	*Hospital and Health Boards Act 2011*
Forensic Examination	The forensic examination consists of obtaining a history as to the nature of the assault to guide the subsequent physical examination. It also includes interpretation of injuries and the collection of forensic samples as it relates to the alleged sexual assault. A Sexual Assault Investigation Kit (SAIK) is used to collect DNA evidence	Queensland Government Interagency Guidelines for Responding to People Who Have Experienced Sexual Assault.
Child	Under the age of 18 years For child victims of sexual assault, under the age of 14 years, sexual assault medical and forensic examinations should be performed by a medical officer with appropriate paediatric skills including child protection and/or sexual assault medical examination training or skills.	Queensland Health Guideline: Conducting Child Sexual Assault Examinations (Document Number # QH-GDL-943:2015
Trained Clinicians	Forensic Examinations can be provided by: • Forensic Physician • Medical Officers who have received training in sexual assault examination • Senior Medical Officers accessing phone support from Clinical Forensic Medicine Unit • Government Medical Officers • Forensic Nurse Examiners (postgraduate qualification in Forensic Medicine) • Sexual Assault Nurse Examiners. Nurses trained in sexual assault examinations having completed a recognised short-course eg SANE 40CPD short course)

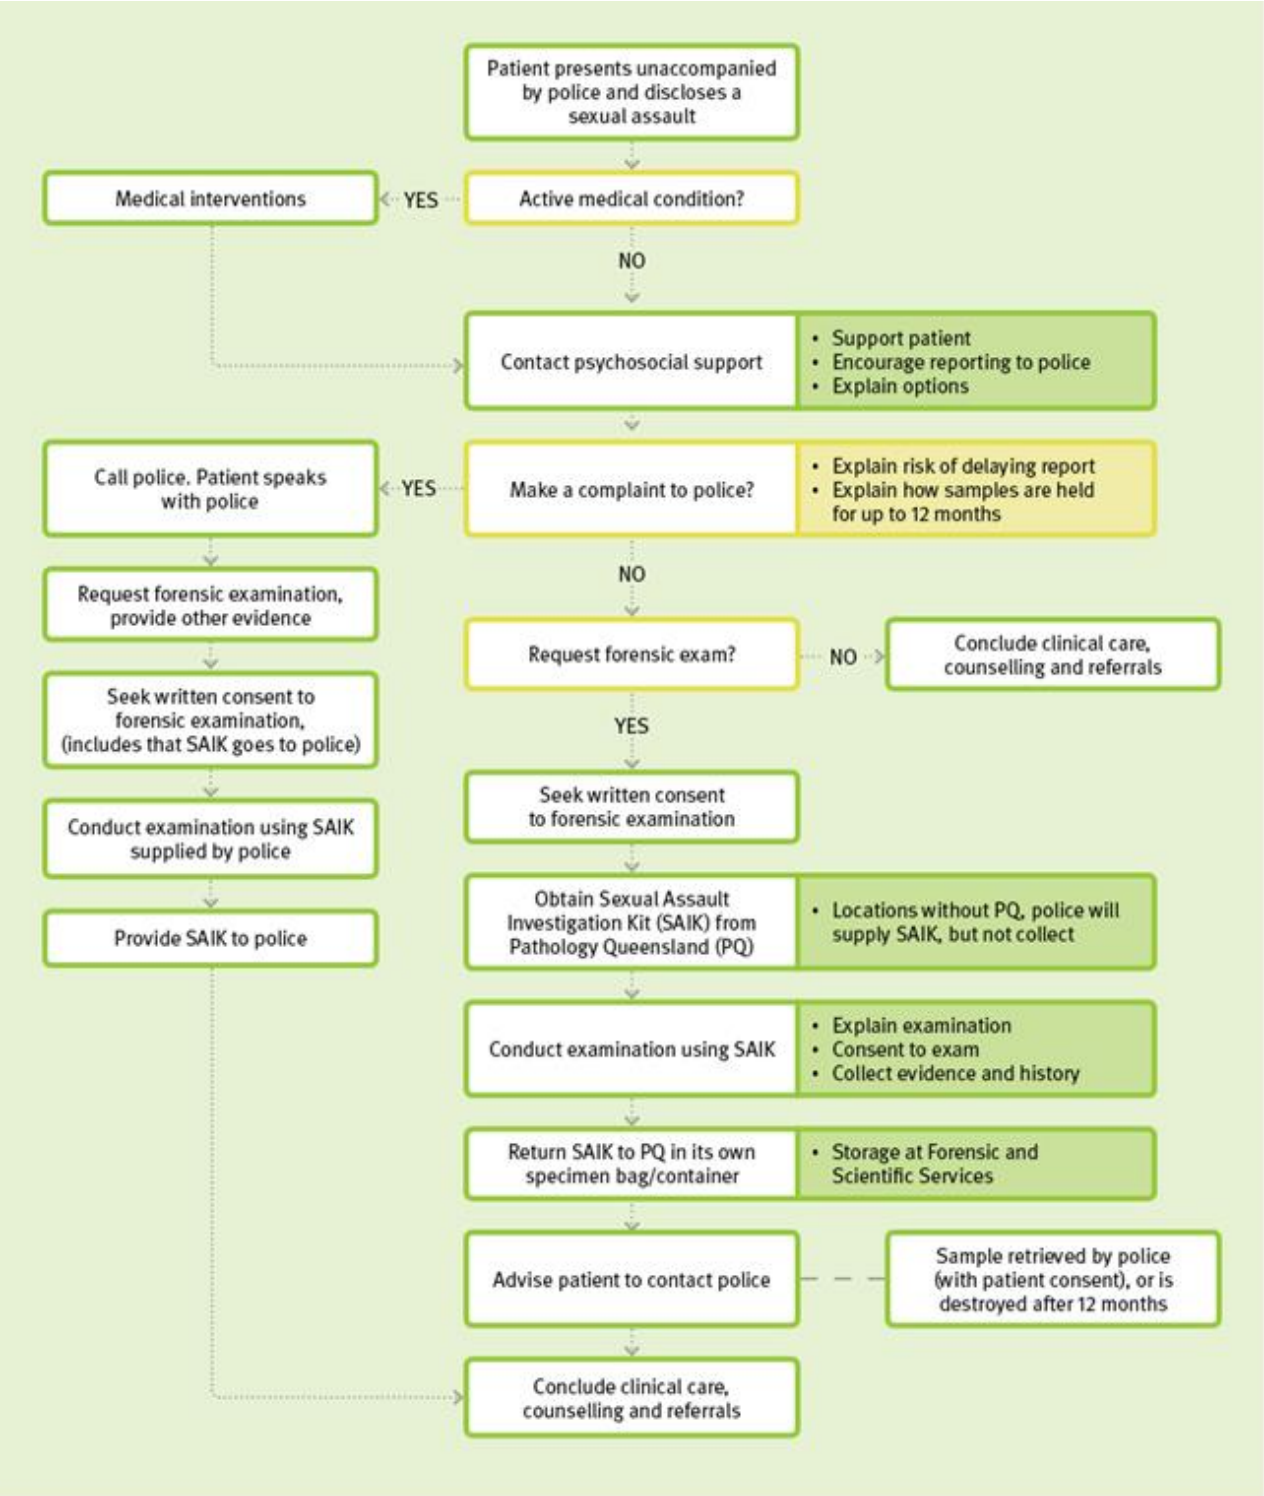
Attachment 1: Emergency Department sexual assault management pathway



Attachment 2: Detailed clinical interventions

Hepatitis B risk assessment and management post sexual assault

If immunised: pathology testing only to confirm immunity and review and follow up of Hepatitis B status. This may be done at follow up.

Hepatitis B Immunoglobulin is not routinely required.

If no previous immunisation, or incomplete immunisation then start the immunisation course or give a booster (i.e. only one or two prior doses).

Consider 400 units IM Hepatitis B IG in a non-immune patient within 72 hours particularly if exposure to member of high-risk group for Hepatitis B (Indigenous, injecting drug user, person from countries where Hepatitis B is endemic) or known hepatitis B. This is most effective administered as soon as possible after exposure, however can be delivered up to 14 days post assault. A repeat Hepatitis B IG is also required at one and six months. This may be provided at a sexual health clinic or via a General Practitioner.

https://immunisationhandbook.health.gov.au/resources/handbook-tables/table-post-exposure-prophylaxis-for-non-immune-people-exposed-to-a-source

Assessing need for HIV prophylaxis post sexual assault

The risk of HIV following sexual assault in Australia is very low. Despite the low likelihood of infection, HIV remains a concern for victims and should be discussed. Giving a realistic estimation of risks may provide reassurance to the victim.

HIV prophylaxis is infrequently required following sexual assault but should be considered if offender was known to be: HIV positive, a male who has sex with males (MSM), an Intravenous Drug User (IVDU) or was from a high HIV risk country such as Sub-Saharan Africa, South East Asia or Papua New Guinea. Transmission risk is also higher if the sexual assault resulted in bleeding from genito-anal injury. *Refer to the Australasian Society for HIV Medicine (ASHM) guidelines for table summarising quantitative risks in different sexual activity scenarios which can be found at:
http://www.pep.guidelines.org.au/index.php/assessment-of-the-risk-of-hiv-transmission/what-is-the-hiv-transmission-risk-exposure#table1

Routine baseline status for HIV should be undertaken. For pre-HIV counselling please refer to the HIV-pre and post-test counselling information and patient brochures located at:

https://www.health.qld.gov.au/clinical-practice/guidelines-procedures/sex-health/hiv-aids

For high-risk cases or any concerns, discuss each case individually with on call Infectious Disease consultant or local Sexual Health Clinic. Many will not be recommended Post Exposure Prophylaxis (PEP). Risk of exposure should be considered depending on sexual assault type and potential sero-prevalence of perpetrator. PEP Guidelines for non-occupational exposure to HIV can be obtained from the ASHM website.

https://www.ashm.org.au/HIV/PEP

Post-exposure prophylaxis starter drug packs should be available for the Emergency Department. These are authorised by the Infectious Disease consultant or Sexual Health Consultant who will advise which

starter pack to use. Most will require Pack A (two drugs) and it is important to follow correct procedures in its administration and documentation. They must be instituted within 72 hours. Follow up of these patients is as an outpatient to Infectious Disease or Sexual Health Clinic or other local arrangement depending on facility location.

Common side effects are nausea, headaches, lethargy (up to 1/3 of patients cease these drugs before completion due to side effects). More serious side effects include liver toxicity. Baseline full blood count (FBC) and electrolytes and liver function tests (ELFT) are required before starting.

Emergency Contraception post sexual assault

If patient has good effective contraception this is not required, e.g. Implanon, Depo provera, Mirena coil in situ, no missed oral contraceptive in last menstrual cycle.

Discuss benefits of “morning after pill”. Generally, this is very safe and should be given if there is any risk of pregnancy.

If indicated, Postinor 1 (Levonorgestrel 1.5mg) up to 72 hours should be taken immediately. It is only effective IF USED WITHIN 72 HOURS OF ALLEGED ASSAULT. It is more effective, the earlier it is used. Consider offering oral maxalon if patient is known to have nausea with the drug. However, very few patients (1.4 – 5.0 per cent) vomit with the progesterone-only emergency contraceptive and antiemetics are not routinely recommended.

If presentation is >72 hours and less than 120 hours, an alternate drug - Ulipristal acetate is likely to be more effective. It is contraindicated in patients with liver disease, asthma requiring steroids, with breast feeding and less-effective if using antacids or Proton Pump inhibitors.

Advise pregnancy test if next period late or different from normal.

Prophylaxis of Sexually Transmitted Infection post sexual assault

Overall risk of STI such as chlamydia, gonorrhea and trichomonas is low. Options of treatment prophylactically in Emergency Department or STI screens in two weeks should be considered depending on patient demographics, likely patient compliance and patient choice.

Chlamydia is the most frequently encountered STI that would be amenable to prophylaxis. After urine PCR (or swabs including throat and rectal if applicable) are collected, Azithromycin 1gm orally stat should be given prophylactically in the Emergency Department if it is difficult to ensure compliance by follow-up of patient.

These patients still require follow up STI screening with a urinary PCR at two weeks post sexual assault as the above does not prevent other infections.

Other bacterial STIs have a very low prevalence in metropolitan Queensland. For high-risk or complex exposures (e.g. multiple perpetrators, perpetrators from population group with high rates of STI), contact Sexual Health Service or Infectious Disease consultant for advice.

If risk is significant, compliance with follow up low or if advice unavailable for such cases give the following two-drug therapy (Please be mindful of Ceftriaxone Resistant Gonorrhoea – if prescribed collect a first pass urine sample for Microscopy, culture and sensitivity (MC&S) and PCR prior to treatment):

1. Ceftriaxone 500mg IM with 2mls 1 per cent lignocaine/Ceftriaxone 500mg IV stat - same if pregnant **AND**

2. Azithromycin 1gm orally stat - same if pregnant.

Follow up after reported sexual assault

All patients should be referred for follow up including pathology results and recommended ongoing testing. Most patients are suitable for medical follow up with their general practitioner, but they should be offered a choice of follow up options.

Patients with more complex or high-risk exposures should be referred to a Sexual Health Clinic or an Infectious Disease specialist for follow-up. A Sexual Health Clinic may also be offered to patients with concerns about confidentiality or those who require access to a free service.

Patients who are commenced on HIV post-exposure prophylaxis should be urgently referred to the Infectious Disease team or the local Sexual Health Service clinic for ongoing supply of medication and specialised management of antiretroviral drugs.

Refer to appropriate Sexual Assault Support Service and/or other psychosocial services such as referral to National Sexual Assault Helpline (NSAH) - 1800 737 732 which operates 24/7 and can provide phone counselling sessions.

Conducting Child Sexual Assault Examinations

1. Purpose

This Guideline provides consistency and best practice for conducting child sexual assault examinations.

2. Scope

This Guideline provides information for all employees, contractors and consultants within Queensland Health and Hospital and Health Services (HHS).

3. Related documents

Procedures, guidelines and protocols:

- Guideline for Care and Treatment Order for a Child
- Guideline for Consent in Child Protection and Management of Complex Care Cases and End of Life Decision Making
- Guideline for Health Professionals Child Safety Capability Requirements
- Guideline for Information Sharing in Child Protection
- Guideline for Reporting a Reasonable/Reportable Suspicion of Child Abuse and Neglect
- Guideline for Responding to an Unborn Child High Risk Alert.

4. Guideline for conducting child sexual assault examinations

4.1 Conducting sexual assault examinations

4.1.1 All medical practitioners shall comply with the informed consent requirements detailed in the *Queensland Health Guide to Informed Decision-Making in Healthcare*, prior to conducting sexual assault examinations in children and young people.

4.1.2 For child victims of sexual assault, under the age of 14 years, sexual assault medical and forensic examinations should be performed by a medical officer with appropriate paediatric skills including child protection and/or sexual assault medical examination training or skills.

4.1.3 For child victims of sexual assault, 14 years of age and over, forensic sexual assault examinations should be performed by a Forensic Medical Officer, Government Medical Officer, Forensic Nurse Examiner or a Medical Officer appropriately skilled to conduct forensic medical examinations.

5. Review

This Guideline is due for review on: 01 June 2020

Date of Last Review: 01 June 2018

Supersedes: Nil

7. Definitions of terms used in the guideline and supporting documents

Term	Definition / Explanation / Details	Source
Child	For the purposes of this document, a child is 'an individual under 18 years of age'.	s.8 *Child Protection Act 1999*
Forensic nurse examiner	Forensic nurse examiner means a nurse who is appointed by the chief executive (health) to perform the role of a forensic nurse examiner. They are employed by the Clinical Forensic Medicine Unit.	Forensic scientific services
Forensic sexual assault examination	This is a specific examination undertaken utilising the Sexual Assault Investigation Kit (SAIK) performed at the request of investigating police.	Forensic scientific services
Informed consent	For consent to be informed, the patient or decision maker needs to be fully aware and have an understanding of the condition, the nature and purpose of the available and proposed healthcare, and potential consequences of each option. Furthermore the patient should be aware of what is likely to occur should they choose not to receive the healthcare. This results from a process of shared decision making and the provision of information in a manner appropriate to the needs of an individual patient or decision-maker.	Queensland Health Guide to Informed Decision-Making in Healthcare (2012)
Government medical officer	A medical officer employed as a government medical officer has the ability to perform procedures under the *Coroners Act 2003*	Queensland Health Human Resources Policy C3
Medical examination	A medical examination is a physical, psychiatric, psychological or dental examination, assessment or procedure and includes forensic examination and an examination or assessment carried out by a health practitioner.	*Schedule 3 Child Protection Act 1999*

Document Title:	CREDENTIALING PROCESS FOR DEFINING A SPECIFIC SCOPE OF CLINICAL PRACTICE FOR NURSES AND MIDWIVES						
Document ID:	[redacted]	Version No:	6.0	Effective Date:	16/06/2022	Next Review Date:	31/01/2026
Document Custodian:	Director of Nursing and Midwifery Workforce Unit			Executive Sponsor:	Executive Director Nursing & Midwifery, Quality & Safety		
Endorsement:	[SIGNED] **Kylie Cookson** A/CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice Committee **Date:** 07/06/2022			Authorisation:	[SIGNED] **Dr Emma McCahon** **Chief Executive** CQHHS Health Service Chief Executive Executive Services **Date:** 15/06/2022		

Statement

Relevant nurses and midwives are required to be credentialed to have a defined specific scope of clinical practice (SoCP) granted to them before they undertake identified clinical practices or activities. This requirement is determined by the Credentialing and Defining the Scope of Clinical Practice Health Service Directive and the Central Queensland Hospital and Health Service (CQHHS) Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice (SoCP) Committee.

Person Centred Care Statement

CQHHS' intent is to deliver high-quality care that is safe, of value and to provide an ideal experience for consumers, their carers and family. Person-centred care is the foundation for achieving this. CQHHS will focus on delivering person-centred care to enable the success of achieving better outcomes for consumers, better experience for consumers and staff; and better value care. CQHHS will support consumers to engage as partners in their own care and ensure the consumers' health literacy is considered.

Intent/Purpose

This document:

- Outlines the nursing and midwifery roles within the HHS that are required to undergo the credentialing for defining a specific scope of clinical practice process.
- Describes the application and renewal processes which enables nurses and midwives to be credentialed to hold a defined specific scope of clinical practice within the CQHHS.
- Outlines the process to authorise a temporary scope of clinical practice.
- Outlines the process to mutually recognise a health professional's scope of clinical practice.
- Defines the maximum duration of a scope of clinical practice.
- Sets out the requirements for maintaining the register of nurses and midwives who intend to engage in a defined, specific SoCP within the CQHHS.
- Describes the appeal process when an application for credentialing of a defined, specific SoCP within CQHHS is denied, withheld, limited, or granted in a different form.
- Ensures all credentialing decisions are professionally led with appropriate nursing and midwifery representation and involvement from a multidisciplinary team.
- Outlines the reporting obligations to the CQHHS Board and Department of Health.

Scope

This document applies to all nurses and midwives and managers of nurses and midwives (permanent, temporary, casual and contract) who hold a specific scope of clinical practice qualification as identified in this document and who are requesting to utilise this qualification to be authorised to practice with a with a specific scope of clinical practice within CQHHS.

Policy

Credentialing refers to "*The formal process used to verify and review the qualifications, experience, professional standing and other relevant professional attributes of health professionals for the purpose of forming a view about their competence, performance and professional suitability to provide a safe, high quality healthcare service within specific environments*" (Australian Commission on Safety and Quality in HealthCare, [2015].

The CQHHS credentialing process is different from that of independent professional organisations who may also provide professional recognition through a "credentialing' process based on specific qualifications through a professional credentialling process (for example Australian College of Mental Health Nurses, Australian College of Children and Young People's Nurses or Australian Diabetes Educators Association). This process is for professional recognition and DOES NOT authorise a scope of practice within the organisation.

The SoCP for each advanced practice nurse or midwife applicant is highly individualised and therefore, determined by the environment in which the applicant is educated, experienced, competent, and authorised to practice within.

Requirements specific to nurses

- Nurses undertaking specific procedures or practices that require specific qualifications and training must have a current documented authorised SoCP.
- Privately-practicing nurses working within Queensland Health facilities, but not employed by Queensland Health need to be credentialed and have a current documented SoCP covering all work performed.

Requirements specific to midwives

- Midwives undertaking specific procedures or practices that require specific qualifications or training have a current documented authorised SoCP.

The CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice (SoCP) Committee applies the following principles as outlined in the Credentialing and defining the scope of clinical practice | Health service directive | Qld Health when reviewing applications and making recommendations for a credentialed nursing or midwifery SoCP within CQHHS.

Nurses or midwives are not authorised to perform the Specific SoCP or role associated with their qualification within Central Queensland Hospital and Health Service facility until they have received approval to do so by the Chair of the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice (SoCP) Committee via formal letter.

Specific Scope of Clinical Practice

The following table identifies the roles and maximum duration of credentialing approval outlined within the documents, by the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice Committee.

Scope of Clinical Practice	Maximum Duration
BCG and Tuberculin testing	3 years
Cervical Screening	3 years
Diabetes Educator (Nurse)	3 years
Forensic Nurse	3 years
Immunisation Program Nurse	3 years
Rural and Isolated Practice Registered Nurse (RIPEN)	3 years
Sexual Assault Nurse Examiner (SANES)	3 years
Sexual Health Program Nurse	3 years
Stomal therapy Nurse	3 years

The duration of the credentialing approval is usually three years however, this may be:
- Reviewed if the individual's role and responsibilities change
- Withdrawn if the nurse or midwife does not meet the CQHHS professional practice and conduct standards.

Initial Application Process

The line manager of the individual nurse or midwife is responsible and accountable to ensure that the nurse or midwife has been informed of the credentialing requirement for a defined SoCP, having been directed to this document and the relevant procedures, protocols and forms.

Step One:
The clinician seeking credentialing is to complete the relevant Specific Scope of clinical practice application form for the specific SoCP being requested. This is available from the Nursing and Midwifery credentialing site. The completed form is to be emailed to [redacted]

Step Two:
Following receipt of the completed application form, a link will be generated for the CGOV system and will be sent to the applicant; via the email address provided in the application form, to enable uploading of the required documents identified on the application form.

If this service is new to the facility in which the clinician practices or is a new role that meets the requirements for credentialing the service lead needs to complete the new service model application form in addition to other requirements outlined for each role.

The application for the credentialing process is reviewed by the Assistant Director of Nursing and Midwifery Workforce initially to ensure all requirements are included and then submitted for consideration to the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice Committee.

The application form and required documentation shall be placed on the agenda for consideration at the next committee meeting.

If a nurse or midwife commences employment with CQHHS and urgently requires consideration of credentialing this will be managed as an out of session endorsement.

Nurses or midwives who are utilising a specific SoCP prior to the development of this procedure are to continue using their specific SoCP if it is a requirement of their position but, will need to have an approved specific SoCP within three months of this policy being published as outlined in the transition arrangements in the documents.

Approval Process

All applications are reviewed by the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice Committee at the next scheduled meeting. The Chair and a minimum of two committee members must review each application document. Subsequently the committee will review and endorse the application. The scope of clinical practice endorsed by the committee must be clearly documented in the minutes and the scope of clinical practice register.

The Executive Director of Nursing and Midwifery Services (EDNMS) approves the recommendation from the committee. The applicant and the line manager receive notification of the outcome of the SoCP application.

Interim Credentialing

Interim credentialing to practice in a defined, specific SoCP may be recommended by the chair of the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of clinical practice (SoCP) Committee for a maximum of three calendar months or, until the next scheduled meeting of the committee in the following circumstances:

Interim credentialing approval to practice in a defined, specific SoCP may be recommended by the chairperson of the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice (SoCP) Committee for a maximum of three calendar months or, until the next scheduled meeting of the committee in the following circumstances:

- The nurse or midwife commences employment in CQHHS, and their role requires a defined SoCP.
- The nurse or midwife gains the qualification that enables practice within a defined, specific SoCP which is required or recommended for that role.
- In emergent situations as deemed appropriate by the EDNMS.

The chair will not grant interim credentialing until all required and/or requested relevant documents have been received and are deemed by the chair as complete.

The chair shall notify the applicant and their line manager within one working day of the interim approval being granted. The period of interim credentialing shall be a maximum of three months and full consideration will occur at the next committee meeting where the documents of the applicant being granted interim credentialing shall be reviewed.

An applicant can only receive interim credentialing approval once and the period of interim credentialing approval cannot exceed three months in total.

The following conditions apply to the granting of an interim SoCP:

- Approval will not exceed three calendar months
- An interim SoCP cannot be renewed
- Must be tabled at the next scheduled CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of clinical practice (SoCP) Committee meeting.

Mutual Recognition of Authorisation and Scope of Clinical Practice

If a nurse or midwife works under exactly the same SoCP in more than one Queensland Hospital and Health Service, a mutual recognition process may be undertaken to grant a mutual recognition SoCP for Central Queensland Hospital and Health Service. The CQHHS must obtain a copy of the originating HHS application form, the minutes of the meeting when the SoCP was granted and the applicants' SoCP approval letter.

The expiry date of the CQHHS approved mutual recognition SoCP must not exceed the expiry date of the SoCP approval granted by the HHS that originally granted the application. The Executive Director of Nursing and Midwifery must review and endorse the application for mutual recognition. The mutual recognition must be ratified at the next committee meeting.

Renewing Authorisation Status

Once the initial application is endorsed by the committee it is valid for a 3-year period unless a review is initiated.

Step One:
The applicant and line manager will receive a renewal reminder 3 months prior to the expiry date with an application form attached. Complete the Specific Scope of clinical practice application form and email to:

[redacted]

Completed application forms need to be returned within 2 weeks of the renewal reminder.

Step Two:
Following receipt of the completed application form, a CGOV system link will be generated and will be sent to the applicant; via the email address provided in the application form, to enable uploading of the required documents identified on the application form.

The renewal application on CGov needs to be submitted no later than 6 weeks prior to the expiry to allow sufficient time for administrative processing and committee review and endorsement. It is the applicant's responsibility to ensure these timelines are met to avoid expiry of the approved SoCP.

Nurses and midwives who have not completed the process steps outlined, will not be considered by the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice Committee to have credentialing approval on the register for their specific SoCP and therefore will not be authorised to practice within the CQHHS.

The same scope of clinical practice SoCP credentialing is not automatically granted. Documentation required will be as per Appendix 2-10 Statements.

Where legislation necessitates retraining requirements then renewal of credentialing shall be identified by the committee.

All nurses and midwives who have been previously listed on the credentialing register, but who have not submitted an application to renew their credentialing at least 4 weeks prior to expiry date will not be considered at the next committee meeting.

This will result in the nurse or midwife not being authorised to practice or to perform any activity associated with their additional qualification past the credentialing expiry date until such time as their renewal application has been endorsed by the committee.

If the role requirements of the nurse or midwife's position demand that they require credentialing to practice within a defined SoCP to continue in that position, then their position may be subject to review by their line manager in consultation with the Executive Director of Nursing and Midwifery Services.

Maternity or Extended Leave

Individual nurses or midwives who have been on leave for a period of 12 months or more are not authorised to independently practice the activities that are related to their intended defined specific SoCP until their application has been submitted and approved by the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of Clinical Practice (SoCP) Committee.

Reporting of Authorisation Breaches

Breaches in credentialing processes and SoCP may be identified by a supervisor/manager/director in the workplace during consultation or induction. If there is a breach in credentialing i.e., notification that a practitioner has commenced work before credentialing for a defined SoCP has been approved or, a practitioner has been working outside their current SoCP, the breach is to be immediately reported to the EDNMS.

If notification is required, a Breach Notification Report Form is to be completed and forwarded to the EDNMS for signing and reporting to the Practice Leader Quality Safety Risk & Data Management. If a breach is identified through a clinical incident that was rated as a high risk or SAC1 event, or an incident which may result in media attention, a brief is to be prepared urgently for the HSCE who will provide an immediate report to the Chief Health Officer.

Practitioner request to review SoCP

A practitioner may voluntarily request a review of their SoCP at any time. This is to be recognised and encouraged as appropriate professional conduct. Where the requested change of SoCP is incompatible with service delivery needs, this should be resolved using relevant human resource management procedures, but with a primary focus on patient safety.

Appealing a Decision

- To appeal a decision made by the CQHHS Nursing and Midwifery and Health Practitioner Credentialing and Defining Scope of clinical practice (SoCP) Committee, a request for reconsideration must be made in writing by the applicant and submitted to the secretariat of the committee within 30 days of receipt of Credentialing outcome letter. The applicant must clearly articulate why a reconsideration of the committee's decision is requested and provide evidence to support the request.
- The individual nurse or midwife should not undertake practice within the defined specific scope of clinical practice until the outcome of an appeal has been determined.
- The Chief Executive will form a review group of a minimum of three relevant independent clinicians which will include:
  - Nursing or Midwifery Director and/or Director of Nursing
  - Nurse or Midwife with the SoCP relevant to the application.
- This committee will be convened within 20 days of receipt of an appeal. The review group will study the request for reconsideration and the additional evidence to support this request. The outcomes of the committee may include:
  - Confirmation of the original decision regarding SoCP, *or*
  - Requirement for an amendment of the original decision which may include conditions.

During each stage of the credentialing and SoCP processes, compliance with natural justice and procedural fairness must be appropriately managed and adhered to.

The appeals process:

- An applicant may lodge an appeal to the committee through the Secretariat.
- The secretariat will ensure the appeal is processed through the committee.
- An appeal committee will be convened independent to the credentialing committee.
- The Appeals Committee will consist of a relevant lead in the SoCP, an independent nurse or midwife, senior nurse or midwife, a relevant Health Professional and a relevant peer.
- Members of the Appeals Committee will ensure any conflicts of interest are declared.
- The Appeals Committee will comply with the Health Service Directives/Policy.
- The Appeals Committee will meet within one week of the minuted applicant appeal.
- The Appeals Committee chairperson will review the Appeals Committee membership prior to meeting to ensure the committee has the expertise, training and independence necessary to participate in the process and assist in the decision being appealed.
- The appointment length of the Appeals Committee will be for the duration of the resolution of the matter under consideration.
- The outcome of the appeals processes will be included in the Credentialing committee agenda to ensure outcome is communicated with members.

Clinical Documentation

Clinical documentation in the health record must be accurate, timely and needs to reflect the entirety of patient care provided, showing evidence of clinical reasoning and decision-making. The documentation must incorporate diagnostic specificity wherever possible and link treatment to diagnoses within the clinicians' scope of practice.

Roles & Responsibilities

Individual Nurses or Midwives

- Supplying their completed application form and all required and requested documented evidence through C-Gov of the educational components, professional standards and competency requirements relevant to the defined, specific scope of clinical practice.
- Minimum qualifications training, registration, experience and clinical competence required in order for a nurse or midwife to be authorised for a defined scope of clinical practice clinical practice.
- Ensuring that their practice is consistent with their credentialing status
- An undertaking to adhere to the specific compliance requirements of the National Safety and Quality in Health Care Standards, specific care standards, professional practice standards and relevant policy and procedures.

- Undertake successful self-assessment every 12 months or as identified for the specific clinical practice / activity and provide evidence of same.
- Holds a defined SoCP linked to annual performance appraisal development (PAD).
- Apply for renewal of SoCP through the CGov data base for the continuation of an existing scope of clinical practice prior to expiry of current SoCP.

Nursing Director or Director of Nursing

- Referral to the committee secretariat, where it has been identified that the standard of practice requires a defined scope of clinical practice to be granted for the organisation.
- The peer review process of assessment of credentials and clinical competence of nurses / midwives who apply to have a defined scope of clinical practice granted.
- Notify the committee if a visiting nurse or midwife not employed by CQHHS requiring SoCP.
- Ensure relevant audits are completed by an appropriate clinical peer.

Line Manager Responsibilities (NUM, Team leader or DON in rural facilities)

- Ensuring yearly updates, mandatory training and PAD are completed yearly as per CQHHS policies, by all staff recognised with a SoCP and in line with role requirements.
- Maintain a register of current staff with SoCP at ward level and reporting any breaches of SoCP to Nursing Director/ Director of Nursing and the committee through the Executive Director of Nursing and Midwifery.
- Notify the committee if a visiting nurse or midwife not employed by CQHHS, is requiring an approved SoCP.

Nursing and Midwifery Workforce Unit (NMWU)

- The NMWU Administrative Officer is the secretariat of the committee.
- Ensuring current data corresponds with C-Gov Credentialing system.
- Ensures the committee minutes are appropriately documented and all new applicants are added to the C-Gov AHPRA app (linked to AHPRA Personal Identification Exchange (PIE) system).
- C-Gov AHPRA app will ensure verification of the practitioner's current registration status through the AHRPA PIE system, and NMWU will report any breaches or changes in conditions or notifications to the EDoNM and the committee.
- Ensure all new applicants are entered into C-Gov data base and renewal reminder of SoCP is emailed out to applicants three (3) months prior expiry of SoCP.

Committee

- Reviewing the applications as per education provided, and in line with the committee terms of reference (TOR) in line with legislation, and State and local policies.
- Using applied knowledge to assign recommendation for either SoCP endorsement, the approval for SoCP with limitations/restrictions or the refusal to grant SoCP approval.
- Comply with principles of natural justice and procedural fairness as a committee member, through declaration of conflicts of interest and acting in a manor free of prejudice.
- Ensure clear accountability of the credentialing and authorisation for SoCP processes and seek advice when unclear applications for SoCP.
- The committee will not consider an incomplete application or make recommendations 'pending' further information.
- Ensuring SoCP is aligned with the Clinical Service Capability Framework (CSCF) of each SoCP application.
- Reporting and maintaining clinical governance with current National Safety and Quality Health Service Standards: Standard 1 Governance for Safety and Quality in Health Service Organisations.

Appendices

- Nil

Definition of terms

Term	Definition	Source
Appeals Committee	The Appeals Committee will be a specially convened independent committee, formed with a minimum of 5 specialist nurses or midwives and allied health practitioners. The Appeals Committee will be convened for the purpose of hearing an individual appeal and will comply with health service directives and policy.	
C-Gov data system	The C-Gov data system is a supported online interface for authorisation and credentialing of health professionals. The system offers an interface for credentialing officers, managers, individual applicants and committees. The system offers the ability to report on the authorisation and credentialing processes in the HHS.	

Clinical Service Capability Framework	The framework outlines the minimum service requirements, staffing, support services and risk considerations for both public and private health services to ensure sage and appropriately supported clinical service delivery. The Clinical Services Capability Framework for public and licensed private health facilities CSCF v3.2	Queensland Health
Competence	Competence is the application of knowledge and skills in the interpersonal relations, decision making and performance consistent with the professional practice role.	
Credentialing	The formal process used to verify and review the qualifications, experience, professional standing and other relevant professional attributes of health professionals for the purpose of forming a view about their competence, performance and professional suitability to provide a safe, high quality healthcare service within specific environments.	Australian Commission on Safety and Quality in Health Care. Credentialing health practitioners and defining their scope of clinical practice: A guide for managers and practitioners. December 2015.
Credentials	The practical experience, qualifications, professional awards and statements of competency issued by an authorised and recognised body that attest to a health professional's education, training and competence and relevant practical experience.	
Scope of Clinical Practice (SoCP)	The extent of an individual health professional's approved clinical practice within an organisation based on the individual's credentials, competence, performance and professional suitability and the needs and capability of the organisation to support the health professional's SoCP	Australian Commission on Safety and Quality in Health Care, Credentialing health practitioners and defining their scope of clinical practice: A guide for managers and practitioners. December 2015.
Scope of Practice	The full spectrum of roles, functions, responsibilities activities and decision-making capacity that individuals within that profession are educated, competent and authorised to perform	Nursing and Midwifery Board of Australia. Framework: Decision making framework for nursing and midwifery
Secretariat	Administration support for the committee and credentialing officer for the Nursing and Midwifery C-Gov System.	
Temporary Scope of Clinical Practice	Temporary SoCP may be used in circumstances when the services of a health professional without SoCP are required at very short notice or, where it is not possible to complete a full application process prior to the health professional commencing. This process strikes a balance between risks of patient harm which arises from a failure to provide an appropriately skilled health professional in a timely manner against the risks of patient harm arising from processes with reduced authorisation or credentialing requirements with less checks and balances in place.	Credentialing and defining the scope of clinical practice for medical practitioners and dentists: a best practice guideline (QH-GDL-390- 1:2017)
Immunisation Program Nurse (IPN)	Under the provisions of the Medicines and Poisons (Medicines) Regulation 2021, only appropriately authorised immunisation program nurses are able to administer and supply scheduled medicines as specified in the Extended Practice Authority 'Registered Nurses' Part D refers to 'immunisation program services'. This part provides the authority for registered nurses to administer vaccines, subject to certain limitations.	Queensland Health Source: Registration and qualifications | Queensland Health

Cervical Screening provider	A cervical screening provider has completed a recognised cervical screening training course in order to provide cervical screening services, and to monitor and maintain their clinical competency standards in line with the National Competencies for Cervical Screening Providers.	Queensland Health Source: Non-medical cervical screening providers | Queensland Health
Rural and Isolated Practice Endorsed Registered Nurse (RIPEN)	A registered nurse who has completed appropriate study in Rural and Isolated Practice, holds an endorsement, with the Australian Health Practitioner Regulation Agency, "under section 94 indicating that the registered nurse is qualified to obtain, supply and administer limited schedule 2, 3, 4 or 8 medicines appropriate to the registered nurse's scope of practice within the meaning of the current poisons standard under the Therapeutic Goods Act 1989 (Cwlth), s. 52D, to the extent necessary to practise nursing in a particular area and described and listed under the relevant drug therapy protocol, Chief Health Officer standing order or health services permit that must be compliant with relevant State and Territory legislation".	Nursing and Midwifery Board – Endorsement of scheduled medicines for registered nurses (rural and isolated practice)
Sexual Health Program Nurse (SHP)	A registered nurse who is authorised under the provisions of the Medicines and Poisons (Medicines) Regulation 2021, to be able to administer and supply scheduled medicines as specified in the Extended Practice Authority 'Registered Nurses' Part C- Sexual or reproductive health Services	Queensland Health Extended Practice Authority - Registered Nurses (health.qld.gov.au)

Sexual Assault Nurse Examiner (SANE) Credentialing Application Form

Information included on this application is for the purpose of credentialling and defining the scope of clinical practice as a SANE.

Applying for: New Application □ Renewal Application □

First Name	Last Name
Previous name: Please include previous name if that appears on certificates	
Contact Details Address:	Email:
Telephone:	Mobile:
Position:	Facility:

NEW APPLICATION (requirements)

□ SANE credentialing application form completed and signed
□ Current curriculum vitae (CV)
□ JP certified copies of qualifications – Evidence of completion of the accredited SANE course (Central Queensland University) or Forensic Nurse Examiner (FNE) course
□ Australian Health Practitioner Regulation Agency (AHPRA) registration
□ Current Career Success Plan (CSP) (first page only – signed by applicant and line manager)
□ Mandatory Training Report

RENEWAL APPLICATION (requirements)

□ SANE credentialing application form completed and signed
□JP certified education qualifications acquired since the last application
□ Current CV
□ AHPRA registration
□ Current CSP (signature page only – signed by applicant and line manager)
□ Recency of practice log
□ Clinical work submitted to quality activity mechanisms including clinical audit, peer review etc. *Please describe*
□ Mandatory training report
□ Professional development
- minimum of 50% attendance at SANE/FNE Community of Practice (SANE-FNE CoP) meetings (bi-monthly)
- minimum of 50% attendance at HHS sexual assault service meetings
- attendance at the Clinical Forensic Medicine Unit SANE-FNE CoP annual forum

□ One page (maximum) reflection on a case
□ Cultural competence training by employer complete

By signing this form, you agree that you have submitted all required and appended documentation to complete the application form and that the information provided is true and correct. Only a signed SANE credentialling application form with all tick boxes checked will be processed.

Please submit your scope of clinical practice application with all required documents to the appropriate Nursing and Midwifery Director/Assistant Nursing and Midwifery Director (or equivalent) for assessment.

Subject: SAIK feedback

Hi Adam and Jacqui,

Below are entries from the SAIK non-conformance log we had created earlier this year on Teams.

The entries below have been populated by the Forensic Property Point at receipt.

For the majority, the issue identified is the paperwork not in the CSPB, which was the topic of our discussion earlier this year and the issue identified in the communication sent to practitioners in March.

Date	QP number/Exhibit barcode	Patient Surname	Examining Clinician	Issue
[redacted]	[redacted]	[redacted]	[redacted]	Blood sample in SAIK (returned to QPS
				SAIK not packaged correctly. Deliverec
				SAIK not packaged correctly. Deliverec
				SAIK not packaged correctly. Deliverec
				Undies packaged in SAIK
				No SAIK medical notes
			[redacted]	Paperwork not in CSPB
				Paperwork not in CSPB
				Paperwork not in CSPB
				Paperwork not in CSPB
				Tox blood kit sealed within SAIK, place
				Paperwork not in CSPB
				Paperwork not in CSPB

[redacted]	[redacted]	[redacted]	[redacted]	Paperwork not in CSPB
			[redacted]s	Paperwork not in CSPB
		[redacted]		Paperwork not in CSPB
				No SAIK medical notes
			[redacted]	1 swab packaged separate to SAIK

Please let me know if you require any further information.

Thanks,
Paula

Importance: High

Good Afternoon,
Jacqui has asked me to share the following with the SANE-FNE CoP.

Kind regards
Mel

Dear colleagues

Since March 2022, colleagues in Forensic and Scientific Services have been collecting SAIK non-conformance on a log.

From March 2022 through to July 2022, there have been 18 entries:

- *No known examining clinician identified in six of the entries*
- *Nursing personnel identified in four of the entries*

- *Medical personnel identified in eight of the entries*

For the majority, the issue identified is the paperwork not placed in the clip seal plastic bag prior to placing it in the Just in Case/Queensland Police Service Sexual Assault Investigation Kit (JIC/QPS SAIK).

In March 2022, a SBAR regarding packaging of swabs, and other biological specimens collected in a JIC/QPS SAIK was distributed. The SBAR is also available at https://qheps.health.qld.gov.au/fss/forensic-services/response-to-sexual-assault under the Sexual assault investigations kits (SAIK) heading.

To lessen risk of contamination, may I ask that colleagues re-visit the document and ensure that practice conforms with the process for packaging.

Warm regards

Jacqui

Through to July

QUEENSLAND HEALTH VISION A world class health system for all Queenslanders

Queensland Health acknowledges the Traditional Custodians of the land across Queensland, and pays respect to First Nations Elders past, present and future.

Report into interviews conducted with police officers and civilian officers of the Queensland Police Service concerning the methods, systems and procedures for the collection and testing of biological material for forensic DNA testing, pertaining to the Commission of Inquiry into Forensic DNA testing in Queensland.

Introduction

1. My full name is Mark William Ainsworth and I am a former Queensland Police Service (QPS) officer with 38 years of service, resigning from the QPS in May 2018 to accept a position with the Queensland Racing Integrity Commission as the Deputy Commissioner from May 2018 until July 2021 when I retired.

2. During my police service I performed duties as a general duties officer, surveillance officer, investigator, District Duty Officer, Detective Inspector, Crime Services, Detective Superintendent, Regional Duty Officer and Director of Corruption Operations at the Crime and Corruption Commission. I performed external roles at the Australian Crime Commission as the Queensland Manager and also the National Head of Determination for the High-Risk Crime Groups. I also had the opportunity to work on the Fitzgerald Commission of Inquiry (COI), the Queensland Floods COI and the Royal Commission into Trade Union Governance and Corruption.

3. During my policing career I attended numerous serious crime incidents and volume crime matters where the detection of DNA and other forensic evidence was involved, in undertaking investigations.

Engagement by the Commission of Inquiry

4. On 23 September 2022 I was engaged by the COI into Forensic DNA Testing in Queensland as a contract investigator. I commenced in this role on 27 September 2022 and undertook interviews with QPS police and staff up until 12 October 2022. I was engaged with the COI to undertake confidential consultation with police officers, especially frontline police officers and their supervisors with an aim to discover;

   (a) Whether there are, and if so, the nature and extent of, issues with the collection, transportation and submission of biological material for forensic DNA testing; and

   (b) Whether there are, and if so, the nature and extent of, issues with the understanding and use of the results of DNA testing.

5. Annexure 'A' is a copy of the 'Terms of Engagement' from the COI in relation to the role I undertook. This document also provided an attachment of a list of core questions that I was required to ask interviewees. In some cases, other questions were also asked of officers, relevant to this COI.

6. Annexure 'B' is a copy of the suggested questions asked of interviewees.

7. In order to fulfill the engagement requirements, initially I contacted officers known to me within the QPS to determine their interest in being interviewed. Throughout the

process these officers also advised me of other officers they felt maybe interested in speaking with me. The process was for these officers to contact them and provide those officers with my contact details should they wish to be interviewed. In addition to this I did have some officers contact me off their own volition seeking interview.

8. Interview appointments were made with 40 officers, however due to a variety of reasons four officers withdrew from being interviewed. The reasons included unforeseen work commitments and a change of mind in wanting to be interviewed. The cooperation level by officers interviewed was very good and clearly highlighted their willingness to speak about their experiences in relation to DNA, consistent with the COI Terms of Reference. The professionalism and forthright responses provided by interviewees, demonstrated a passion and desire to achieve the best results they could for victims of crime, by utilising all available forensic and investigative tools.

9. The officers interviewed appeared genuine in their responses and did not openly go out of their way to criticise the QPS or the Queensland Health Forensic and Scientific Services (QHFSS), but to offer honest suggestions on what needed to change in order to benefit victims of crime and the community in general.

10. It was made clear from the outset that there was no compulsion for any officer to be interviewed and it was purely voluntary on their behalf. It was explained to all officers that the Commission were happy to proceed on a confidential basis, in that the officers' names were not to be mentioned in any document forwarded by me to the Commission. Annexure 'C' refers. It was explained to officers if they wished to provide their names they could and their names would be provided to the Commission. In total three officers out of the 36 interviewed were happy to provide their names.

11. In order to maintain confidentiality, officers were allocated a Person Number and that was the only reference to officers. The person number and associated officers name was retained by myself and not passed to any third party. At the commencement of the interview some antecedent type questions were asked including the officer's role, rank, years of service and Region/District they currently worked in. At the conclusion of asking these particulars, officers were asked if they consented to the digital recording of their responses to my questions. If officers consented then the digital recording commenced after the antecedent details were obtained. 33 officers consented to being digitally recorded.

12. Interviews were conducted of officers from across the state in order to obtain the various geographical challenges relating to issues around DNA, collection, transportation and analysis. A focus of the interviews was largely on front line officers ranging from investigators to supervisors, officers in charge of work units, forensic officers and prosecutors.

13. The breakdown of **positions of officers** and ranks interviewed are as follows:

(a)	Investigators	12
(b)	Scenes of Crime Officers (SOCO)	8
(c)	Scientific Officers	6
(d)	Prosecutors	7
(e)	Forensic Coordinators	2
(f)	Forensic Managers	1

14. **Ranks of officers interviewed are as follows:**

(a)	Detective Inspector	1
(b)	Inspector	1
(c)	Detective Senior Sergeant	2
(d)	Senior Sergeant	6
(e)	Detective Sergeant	8
(f)	Sergeant	16
(g)	Senior Constable	2

Questioning Sequence:

15. The COI provided 25 questions in general to be asked of interviewees. The first series of questions were asked under the subheading of **Collections** and related as follows:

    (a) Questions 5 all officers except prosecutors.

    (b) Questions 7,8 to officers not forensic officers or prosecutors

    (c) Questions 8 – 11 for forensic officers only

    (d) **Forensic Medical Examinations** was the next subheading and contained the following.

    (e) Question 12 to all officers except prosecutors

    (f) Officers who answered yes to Question 12 were then asked questions 13 – 18.

16. **Results of DNA testing** was the next subheading and contained the following.

    (a) Questions 19 – 24 was asked of all officers interviewed

17. **Other issues** was the final subheading and all officers were asked this question.

18. During the course of the interviews with officers the most common issues they were concerned about across the board included.

    (a) QHFSS results a lack of understanding across the board of what results meant and the difficult nature to interpret results.

    (b) QHFSS results results such as 'No DNA detected' and 'DNA insufficient for further processing' have had a huge impact on most officers interviewed. Many officers considered on receiving results of this nature nothing further could be done in relation to the DNA the result pertained to, most felt there was no DNA so end of story.

    (c) Several QPS forensic officers were left second guessing their own capabilities as forensic officers when constantly receiving the above-mentioned results. This especially applied to lack of DNA in blood and semen samples.

    (d) Many officers, since learning of what the above-mentioned results actually do mean are concerned that they could have actually requested further testing of the initial results which may have led to a different outcome. Many officers felt the above issue has seriously let victims of crime down and also the community.

    (e) Transportation of DNA and other exhibits from regional and remote parts of the state is an ongoing issue and impacts on timeliness of having DNA samples delivered to the QHFSS facility and for analysis to be undertaken. Officers in these areas and even in some areas closer to Brisbane e.g., Wide Bay Police District spoke of frustrations in the transportation process.

    (f) Almost all Forensic officers believed their equipment was adequate for them to undertake their roles but all indicated the QPS needs to ensure monitoring of international crime scene trends and technology is maintained to ensure best practise.

    (g) Senior Investigators in particular raised concerns with the perceived lack of DNA sampling from persons charged with an indictable offence. Several senior officers (officers in charge) advised they have a focus on ensuring DNA is taken relating to these circumstances and have an expectation their staff to do so. One officer advised the state is sitting at 31% compliance with this particular practise. Other officers advised that it is currently a focus of QPS Management to ensure this practise is undertaken by all staff involved in the arrest of a person on indictable offences.

Collection

19. Officers interviewed stated attendance at crime scenes is their bread and butter duties, and policies and procedures for major serious crimes are consistent and have been around for many years. Investigators stated they attend the crime scene and make sure

[redacted]

Mark Ainsworth Witness [redacted]

the scene is secure to enable forensic officers the best possible chances of collecting exhibits for examination including DNA exhibits. Investigators stated that they consult heavily with forensic officers at major crime scenes and work in well with one another. Consultation continues all the way throughout including prioritisation of exhibits to be sent to the QHFSS for analysis.

20. Officers spoke about triaging DNA exhibits and prioritising them to send to QHFSS for analysis. Officer's stated they can only send a certain number of exhibits to the QHFSS at anyone time and priority exhibits will have a quicker turnaround time usually between 3 days to a week. Prioritisation of exhibits involving major crime investigations is undertaken in consultation with investigators, forensic officers including forensic coordinators. Forensic Coordinators interviewed stated they can send 25 exhibits to the QHFSS in a batch and the top five which are listed as a priority one will be analysed first followed by five at a time after that.

21. With respect to volume crime advice was provided that officers can only send through one or a maximum of two exhibits for DNA analysis at a time. The forensic coordinators interviewed stated that they can negotiate with staff at the QHFSS regarding the examination of other DNA exhibits located at the scene.

22. Two investigators stated they could understand the priority system and consider it necessary as the QHFSS has a big workload and consideration has to also be given to other police officers and their investigations that may rely on DNA evidence.

23. SOCO officers provided information about a state-wide project underway in a number of regions in relation to volume crime. If a member of the public phones through a break and enter etc or submits an online report, the report or information is forwarded to a SOCO office for a SOCO to take charge of the matter. SOCO's advised they will contact the victim and discuss what possible evidence is present prior to attending the scene. If a determination is made that there could be evidence at the scene the SOCO will attend and undertake a forensic examination. Their attendance at these scenes can also include advice to the victim about property security and prevention.

24. Forensic officers interviewed stated scientific officers will attend most scenes of major criminal matters and that call is generally up to the forensic coordinator. SOCO officers can undertake most scene examinations but rely on scientific officers for specialist examinations which may include blood splatter patters or impression evidence.

25. One hundred percent of investigators interviewed praised forensic officers in relation to their dedication, quality of work at crime scenes and their ability to located, collect exhibits. SOCOs stated crime scene attendance and collection is their daily tasking and officers stated you adopt a routine to undergo the examination.

26. Investigators were asked about taking DNA samples from persons arrested for indicatable offences. Of those interviewed all investigators who do make arrests for indicatable offences do take DNA evidentiary samples and take the samples themselves. Officers interviewed stated that in the case of taking an intelligence sample, they will check the persons details on Qprime and if they have DNA already on the system they will not take an Intelligence sample. If there is no DNA on the system for

[redacted]

Mark Ainsworth Witness [redacted]

the person, an intelligence sample will be taken. Generally, watchhouse staff will take intelligence samples at the same time as taking identifying particulars.

27. Two officers stated further education is required for front line officers to ensure they understand the benefits and importance of taking evidentiary and intelligence DNA samples. Two officers from the North Coast Region stated their region is currently focussing on the taking of DNA samples and they are encouraging their staff to do so.

28. Investigators stated they rarely have any trouble having forensic officers attend crime scenes either for major crime or volume crime matters. All investigators stated that obviously Homicide, rapes and other serious crimes get forensic officer priority. Investigators in the Brisbane Metropolitan area stated they have scientific officers at their door step and have no issues in getting them to attend scenes. They indicated there was no issues with transportation of exhibits by forensic officers to the QHFSS and for serious offences this occurs in a very timely manner. Investigators stated SOCOs look after volume crime exhibits from locating, lodging as an exhibit and arranging their transportation to the QHFSS.

29. Regional detectives interviewed stated sometimes there is a wait to have scientific officers attend major crime scenes. Officers stated in Queensland scientific officers are based in Brisbane, Coomera, Rockhampton, Townsville and Cairns. On occasions crime scenes have to be locked down for a longer period of time to allow scientific officers to travel and attend the scene. Investigators stated they will always attend when requested.

30. A number of regional and remote detectives identified difficulty in having DNA exhibits sent to the QHFSS mainly based on the tyranny of distance. They stated in major matters if an Investigation Centre has been established, exhibits maybe flown to Brisbane by the exhibit officer during the running of the operation. In other cases, exhibits are stored appropriately in police station exhibit rooms and will be transported to Brisbane when an exhibit run occurs. This can vary depending on the area from once a month to once a fortnight. This can cause significant delays then in getting a result back in a timely manner.

31. Officers stated that in the regional areas, DNA intelligence exhibits (mouth swabs) are mostly forwarded by registered post to Brisbane. Evidentiary samples are hand delivered to ensure continuity and safety of the exhibit.

32. Several investigators commented on the operating hours of the QHFSS in particular not working weekends or public holidays. One Senior Detective provided the following example and a positive resolution arising from this example.

    (a) The officer would like to see staff from the QHFSS be rostered on weekends as on some occasions undue delays are caused in investigations where QHFSS are not working weekends or public holidays. e.g., quick turn arounds for DNA examinations where a murder suspect is outstanding and still in the community, risk to the community.

    (b) [redacted] – the Rape and Murder of [redacted]. The body of [redacted] was found on [redacted]

[redacted]

and significant DNA samples were taken from her body, including a substance that appeared to be a large quantity of semen.. Investigators had no suspects for this violent murder and were keen to solve the matter quickly to ensure public safety. They were advised to submit their Top 5 exhibits for DNA analysis which they did. They were advised of a 5-day turnaround of the DNA analysis. Due to the lateness in the week and the seriousness of the matter the QPS paid overtime for QHFSS staff to work the weekend to ensure the 5-day turnaround commenced asap. A result of no male DNA came back on the Sunday afternoon. A request was made to rework the samples and at 3pm the following Friday a DNA match was obtained which identified a male person. Evidence obtained from further investigations on the suspect accompanied by the DNA match, led to the arrest and successful conviction of the offender.

(c) The ability for the QHFSS to work on weekends/public holidays or be available to work weekends and public holidays can be crucial to serious Crime matters where offenders are outstanding.

Collection – Forensic Officers only

33. Seventeen forensic officers were interviewed as part of this process and were questioned regarding issues relating to the collection of biological material, staffing levels, inability to attend crime scenes, equipment and contamination issues at crime scenes. In relation to equipment sufficiency, all officers interviewed were happy with their current operational equipment and said it was sufficient for completion of their jobs. One officer stated generally if they need equipment they get it promptly. A scientific officer [redacted] stated equipment is currently sufficient, however technical capabilities of equipment is increasing all of the time and the service need to keep abreast of equipment out there. The officer suggested the engagement of a Research and Development officer in Scientific would be valuable with regards to keeping up with current equipment and technological trends for scientific officers and SOCO officers. The officer stated Technical Advisory Groups for each scientific speciality meet yearly. These advisory groups are attended by scientific officers from each Australian jurisdiction and information sharing on trends, technology and equipment are shared.

34. Contamination of crime scenes was discussed and two officers said they have had issues with volume crime where SOCO's may not be able to attend for sometime. One officer stated in 2020, general duty officers were diverted away from attending volume crime matters and SOCO's attended. He stated this only occurred if matters were reported through police link where the jobs were detailed to SOCOs. He stated on receiving the job they review the information, contact the complainant and make an informed decision if there is value in SOCO's attending the job. He stated on attending, the usual crime scene examinations are conducted, however if the complainant has further information (identifying a witness etc) then the SOCO staff will run that out as well. He believes if this occurs a further 15 to 20 minutes is added to each job. The officer stated this creates a risk for contamination at crime scenes by complainants.

35. Another officer [redacted]. Transportation can sometimes

difficult to get to crime scenes in a timely manner. Transportation can include planes, ferries and water police. Time delays to get to crime scenes can have an effect on contamination of scenes but they do the best they can to have a clean scene.

36. Half of the Forensic Officers interviewed stated they did not believe contamination at point of collection is a major issue these days. All Forensic officers have provided their DNA for elimination purposes only. Recorded in a DNA elimination data base controlled by the Inspector, Scientific Services. SOCO's can choose to be advised if they have contaminated a scene. E.g., not wearing a mask when taking fingerprints then their DNA turns up at the scene after DNA examination. Officers could elect at the time of providing their DNA if they wished to be advised of any contamination issues. 90% of the officers who spoke about this process have elected to be advised if their DNA is identified at a scene as in their view, provides good education on how to operate more efficiently at crime scenes in reducing contamination.

37. Almost all of the forensic officers interviewed felt their crime scene collection processes were down pat. A number of officers stated their policies and procedures are very stringent and are governed by NATA requirements. Policies and procedures are managed by the Quality Management Unit, Scientific Services and are very specific regarding collection practises. All policies and procedures are on the forensic intranet and officer's tuff books for in field reference.

38. In relation to staffing, one officer stated the Scientific Section rosters are getting pretty lean. The officer provided the following scientific staff numbers spread over the state:

    (a) Brisbane 5, Coomera 2, Rockhampton 2, Townsville 2, Cairns 5.

39. The officer stated the current burn out rate for scientific officers is currently high due to high workloads and distressing scenes they attend. Another forensic coordinator interviewed stated they would like to see more scientific officers in the state. The officer stated it takes a long time to become qualified as a scientific officer having all authorisations. The officer stated in [redacted] view this impacts on providing a 24/7 response. e.g., Officer stated it took [redacted] 6 years to obtain authorisations relevant to major crime examinations. (Scientific Officers have to have specific authorisations for every skill set they have e.g., Impressions one authorisation, blood splatter patterns – another authorisation).

40. Nine out of seventeen officers interviewed had no issues with staffing levels, two officers as above had the mentioned concerns, two other officers said their roster was affected by staff sickness and two further staff indicated they were short staffed. Contrary to this, an officer interviewed from a remote part of Queensland who is the only SOCO for 230 000km2 was happy that [redacted] was the only SOCO in that area, and whilst [redacted] was always travelling and on-call [redacted] stated there is insufficient work for [redacted] to have another SOCO working with [redacted]

41. All forensic officers interviewed clearly understood their policies and procedures and knew where they could be found for easy reference and how they relate to NATA accreditations. They were happy with the governance around forensic procedures including collection.

[redacted]

Mark Ainsworth Witness [redacted]

42. Officers stated there is currently no refresher course for forensic officers. Officers stated pre-Covid there was an advanced scenes of crime course which forensic officers attended. The officers stated the course ran for one week in Brisbane, once per year and would cover topics such as new crime scene examination techniques, brain storming sessions with other SOCOs from around the state, guest speakers and also provided the opportunity to share ideas and innovation with other officers. Most officers advised that refresher training has ceased, however there is an understanding that a new refresher course is currently being developed for forensic staff. Four officers stated that you could apply to attend a specific course off your own back and generally you would be supported to attend. These courses include blood splatter training which runs for a week.

43. Several officers stated they would like to see refresher training on DNA or even some basic training in understanding what DNA results mean when they come from QHFSS. Several highlighted the COI has uncovered a major issue pertaining to DNA results which many forensic officers were not previously aware of.

44. Ongoing proficiency testing is regular for all forensic officers consisting of the following:

(a) A NATA accredited on-line virtual crime scene product where one person in each forensic office is to complete the session once a year. This learning is called, 'After the Fact.' Advice from several officers is that all trainee forensic officers must compete this course. Formerly every officer had to complete it each year and there was a different level for Sergeants and Senior Sergeants then another level for Constables/Senior Constables.

(b) On job assessment of SOCOs by a supervisor. This occurs once every two years where a supervisor will attend active crime scenes and assess the SOCO undertake a crime scene examination including collection of exhibits, packaging of exhibits and the associated paperwork including data entry.

(c) Scientific officers are assessed every twelve months on every authorisation they possess e.g., Impressions, ballistics – assessed every twelve months.

(d) Scientific officers must complete an 'After the Fact' training module on line every twelve months on their authorisations as well.

(e) Scientific officers are considered 'Experts' in various authorisations and must also undergo a Court assessment every twelve months. This assessment is either done by a senior scientific officer, a prosecutor – QPS/DPP or an investigator. If the officer has not attended court in that twelve-month period then a mock court is held where the officer can be assessed. Such assessments are NATA requirements.

(f) A SOCO, officer in charge stated she undergoes an office audit every twelve months conducted by the Quality Control Manager in line with NATA requirements.

(g) The same officer stated every two years a NATA person will conduct an audit of her office checking dates on consumables, exhibit management. She stated since COVID, these audits have been desk top audits only.

45. Every Forensic officer indicated their initial training was adequate and prepared them well for their future careers in that field. Over the years (15 to 20 years) SOCO training changed in duration from a six-month course to the current twelve-month model which consists of a five week in class training component in Brisbane where staff learn about photography, fingerprinting and scientific work. At the conclusion of this course, they work under the supervision of a Field Training Officer for a period where they are watched, trained and assisted in undertaking SOCO roles. During this period, they are required to meet five competencies. Several senior SOCO's stated the latest course is very good and believe the quality of trainee SOCO's coming through are very good. A forensic coordinator commented that the current SOCO initial training is probably better than previous initial training and the officer has noted the quality of work from these new officers is to a very high level.

46. A number of SOCOs stated after initial training a lot further learning is undertaken on the job as they attend crime scenes, two officers stated most SOCO work is repetitive in nature and SOCOs develop a routine for crime scene examination and collection.

47. Scientific officers stated their training included three residential courses of about 6 weeks duration, each conducted in Brisbane. The training consisted of three modules.

(a) Module 1 this module covered amongst other learnings, DNA education on DNA, presumptive testing and screening techniques.

(b) Module 2 Expert witness training, speciality training including impressions, blood splatter patterns etc.

(c) Module 3 Amalgamation of all training plus training in microscopes, ballistics, bomb scene requirements, radiation scenes.

48. In relation to Module 1 several officers stated QHFSS staff attended and provided education on DNA. This module also included a tour of the QHFSS facilities, only to the extent of what each area did and nothing more detailed as to processes. After completion of module one, officers were paired up with a Sergeant supervisor and worked under complete supervision until deemed competent. Once deemed competent officers could undertake crime scene examinations in relation to module one learnings only.

49. The same process occurred after module two and generally at the conclusion of module three, if deemed competent, officers would generally be signed off to work on their own. Officers stated there was always other more experienced officers available to assist if required.

50. Whilst forensic officers believe their initial training was adequate, most officers indicated they would like to see refresher training re-introduced and would like to see more training in DNA including an educational tour of the QHFSS where they could see the processes utilised by biologists and scientists and obtain an understanding of

the capabilities of testing as well as technical advancements in DNA analysis, at those facilities. As part of further DNA training most officers commented they would like to see explanations on the interpretation of DNA results. Some officers did understand the results. A forensic scientist with the QPS indicated that DNA is rapidly changing and refresher training is critical in the areas of degradation of DNA, nuclear DNA and to further learn on developing trends and collection processes.

51. A forensic coordinator [redacted] stated [redacted] completely understands DNA and has completed Tertiary studies on DNA but has no idea regarding the interpretation of reported results or extraction procedures undertaken by QHFSS. The officer stated further education is required in relation to changing DNA techniques and evolving modern technologies. The officer stated [redacted] has learnt more about DNA from monitoring the DNA COI than what [redacted] has learnt in the last [redacted] years in the field.

Forensic Medical Examinations

52. All investigators interviewed have in the past or currently, had experience with complainants/accused persons undergoing forensic medical examinations. Generally, investigators arrange the forensic medical examination and transport the complainant/accused to the location for the examination to occur. At the conclusion of the examination medical professionals hand the sexual assault investigation kit (SAIK) to the investigating officer for exhibit lodgement and transportation to QHFSS.

53. SOCO's will on occasions attend forensic medical examinations for the purpose of photographing injuries generally at the direction of the medical professional undertaking the examination. SOCO's do not have involvement in taking possession of SAIK. Several SOCO's stated the best understanding of what exhibits they manage and transport is whatever a SOCO locates, collects and takes possession of they will lodge the item/s as an exhibit and take charge of transportation for analysis.

54. All Scientific officers interviewed have not been involved in a forensic medical examination in recent times.

Forensic Medical Examinations – for officers who have been involved

55. Responses to this series of questions was predominantly from investigators. Whilst some SOCO officers indicated attending forensic medical procedures for the purpose of taking photographs they were unable to provide responses to the remaining series of questions under this category.

56. Investigators provided differing outcomes as to who provides medical examinations. Three officers stated the Government Medical Officer (GMO) in their respective areas would provide this service, whilst nine officers stated either the GMO does not provide this service or there is no GMO in their area. Five officers advised that their respective area uses Forensic nurses to undertake these examinations. One officer from a remote location advised the local Doctor who is Head of Emergency willingly assists police with forensic medical examinations.

57. Across the board, investigators stated generally the complainant does not get a choice of the gender for a forensic medical procedure due largely to the difficulty of locating

[redacted]

Mark Ainsworth

Witness [redacted]

Medical professionals to undertake the same. In cases where a male medical professional is undertaking the examination of a female victim/accused, investigators will facilitate a female officer to be present for the examination. Several investigators indicated that forensic nurses are mostly female and no issues occur with gender choice in those cases.

58. Three investigators have had experience where medical practitioners have refused to assist with forensic medical procedures based on inexperience in process and not wanting to be subject to Court processes. One officer from [redacted] provided the following example.

(a) This is very disjointed in his area, and according to this officer very frustrating. Most times they are directed to the [redacted] for forensic medical examinations, other times they go to the [redacted] Neither the [redacted] nor [redacted] hospitals do these procedures

(b) No GMO's in his area.

(c) E.g., [redacted] Rape matter that occurred at [redacted] victim had mental health issues and was under the care of a State Guardian. Investigators contacted the [redacted] who would not receive this complainant as there was another patient they had who could not be in contact with the complainant. Investigators contacted the [redacted] who refused to assist, telling the investigator to attend [redacted] hospital. The investigator advised [redacted] does not perform these tests, they were then told to go to the [redacted] The investigator then contacted the GMO in [redacted] who would not do the examination and redirected them to the [redacted] The investigator contacted the [redacted] again and on this occasion agreed to do the examination provided the state guardian was present.

(d) Whilst this negotiating was occurring the victim's carer took the victim home to get a change of clothes. The victim decamped and injured herself. Sexual assault examination undertaken when she was conveyed to the [redacted] for treatment to her injuries.

(e) This officer relayed another example where he took a sexual assault victim to the [redacted] at 10pm one night. The victim was admitted through emergency then sent to the hospital social worker for consultation. When this was concluded the forensic nurse was contacted and the medical examination was commenced at 3am.

(f) The officer said in these examples, **'Victim Centric'** is a complete failure. He stated he advises his staff to take a laptop to the hospital to take the victims statement whilst awaiting the medical procedure

59. Another officer provided an example of difficulties in forensic medical examinations.

(a) He stated in his area GP's will not assist in forensic medical procedures and provided an example [redacted] - a female was raped at [redacted] she attended the

[redacted] hospital and was refused a medical examination, [redacted] Hospital refused and the victim was driven to [redacted] some three and a half hours away.

(b) The complainant was very cooperative and the examination was undertaken in [redacted] DNA was obtained and a person was arrested for the offence of rape.

(c) The officer said as an OIC of a CIB he is a member of the Sexual Violence Liaison officer network which includes all OIC's of CIBS, CPIU and Crime Intelligence staff. At these meetings they discuss issues particularly withdrawal of complaints to assess what are the prevailing issues with sexual assault withdrawals, solved sexual assaults and rapes. He stated he raised the above example at the meeting. He stated he later spoke to a senior person at the [redacted] Hospital about the [redacted] matter and since that time so far, things have improved.

60. All investigators stated they have never had any issues in obtaining SAIK's, most police stations have a supply and hospitals in some areas also have supplies. This is not an issue.

61. Investigators stated there are varying places where complainants wait to undergo a forensic medical examination. Several investigators stated hospitals in their area have a triage room where the complainant can wait in a private area, others stated that in their area complainants have to be admitted to the hospital through emergency sections, whilst on other occasions complainants wait at police stations, prior to transport to a medical facility for examination. Officers stated for a 'victim centric' approach the triage room is ideal for complainants to wait in. Times vary in waiting for a medical examination depending on the time of day or night, the location and the availability of medical professionals. A couple officers stated on occasions they have had complainants who will not wait for a forensic medical examination, resulting in no forensic medical procedure being undertaken. The officers stated this does not stop the investigation but impacts on the investigation with that lack of possible evidence.

62. Investigators take possession of SAIKs from the medical professional and they arrange transportation to the QHFSS for analysis. As previously stated in this report, the tyranny of distance does impact on delivery times to the QHFSS. Investigators highlighted that forensic officers do not process other exhibits relating to a rape or sexual assault examination until the results of SAIKs come back from QHFSS. Officers stated result turnaround times are varying. One officer provided the following example.

(a) The rape of a female at [redacted] ([redacted] refers). This example is one of a quick turnaround by the QHFSS. Sample was taken on 23 January [redacted] and delivered on 28 January [redacted] to the QHFSS. On 8 February [redacted] processing of the sample commenced. On 2 March [redacted] the results came back to the DNA Management Unit and a phone call was received by the investigator. A profile was identified leading to a criminal charge.

(b) The officer stated the investigator consulted with the QHFSS to have the sample tested quickly as they had a suspect and wanted to execute a search warrant on the suspects residence. He stated QHFSS were helpful on this occasion.

(c) The officer stated in the case of major crimes especially homicide, he personally finds the QHFSS do a decent job in turnaround times.

63. Investigators interviewed from regional and remote areas indicated that sometimes there are delays in getting SAIKs to the QHFSS based upon when the station undertakes exhibit runs to Brisbane. If the matter is urgent (Rape) the investigator will arrange delivery time within 24 to 48 hours.

64. Out of the eight investigators who could answer this question (excluding senior officers who have no recency in this area) seven of the officers stated it is up to the investigating officer to undertake a DNA reference sample from a complainant. One officer stated in his area the forensic nurse will take the DNA reference sample. All officers stated that consent from the complainant is always obtained for this reference sample and there are really no issues with this occurring. One officer stated complainants in his experience have no issue providing the reference DNA sample as the procedure is non-invasive. Officers indicated the DNA reference sample is taken at varying times either before or after the forensic medical examination. If a complainant is waiting a while for the forensic medical examination a statement and DNA reference sample will be taken then. One officer stated it would be good for complainants to have the reference sample taken at the same time of the forensic medical examination, in the interests of complainant's welfare. Other officers did not see this as an issue.

65. A [redacted] officer spoken to regarding the timing of complainant reference samples and forensic medical examinations provided information pertaining to this issue which he was very passionate about.

(a) The officer stated he was aware of a document produced and signed by the Commissioner of Police and several Directors General supporting the taking of DNA reference samples by Medical Practitioners at the same time as forensic medical examinations. He believes the document was titled, 'Response to Sexual Assaults.'

(b) The officer [redacted] stated it concerned the obtaining of a reference sample from a complainant by the GMO at the time of the forensic medical examination. He said two SAIK group reference meetings were held, the last being on 15 December 2021. He said at the first reference group meeting (date he could not recall) attendees were in favour of the above-mentioned strategy occurring, however Dr Adam Griffin would not agree and the matter has not progressed. He said this matter has been ongoing since 2014.

(c) He said the benefit of implementing this strategy was two-fold:

(i) Consideration for the welfare of the complainant - undergoing examinations at the same time rather than two separate examinations.

(ii) Timeliness of the examination of the SAIK and reference sample both arriving at the QHFSS at the same time. Eliminates the SAIK being delivered one day then the sample being delivered at a later time.

(d) He stated an Executive Briefing Note (EBN was submitted after the second SAIK reference group meeting regarding the incident [redacted].

66. Officers interviewed indicated varying times for QHFSS turnaround time for SAIK examinations. One officer indicated he has no issues with the turnaround time whilst others indicated turn around times ranging from 30 days to six months. Another officer commented that there were significant delays in getting these results back. Several investigators indicated delays in getting SAIK results back impacted on the processing of other exhibits collected for the particular offence, as generally no other scene exhibits will be processed until the SAIK results are known. Officers stated that the time delays in having SAIK's analysed impacts on the investigation timeline and consequentially impacts on the complainants. Four officers stated they have no issues with turnaround times for SAIK analysis.

(a) One officer stated he has experienced significant delays in getting SAIK results back in a timely manner to the point of delaying the investigation.

(b) He stated he would have thought the testing of SAIK material by the QHFSS should be reasonably quick in that there is either DNA there or there isn't particularly in the case of rape offences.

Results of DNA testing

67. All officers interviewed were asked questions in relation to the above subheading. It appears advice of results differs in varying areas according to investigators. One certainty is that results are uploaded on Qprime as a supplementary entry usually by the DNA Management unit. Notable differences exist for advice regarding major criminal matters as compared to volume crime matters. Volume crime results are often advised through a supplementary entry on the Qprime system. Investigators stated in the case of major criminal matters generally they will receive a phone call advising of the result from the DNA Management Unit or the forensic coordinator followed up by an email. Two investigators from specialised investigation units maintain a close liaison with QHFSS staff and their forensic coordinators and do not have an issue being advised of results in a timely fashion. Notable differences exist for advice regarding major criminal matters as compared to volume crime matters. Volume crime results are often advised through a supplementary entry on the Qprime system. Some examples of investigators comments are:

(a) Notification of results is pretty good at the moment.

(b) This officer liaises with the QHFSS scientist chasing very specific updates regarding items being analysed. He has found staff at the QHFSS very helpful and forthcoming with information when he contacts them.

(c) He said generally for serious criminal matters he will receive a phone call with the results followed up by an email and an update to the Qprime entry. Emails come from the DNA management unit.

(d) He stated in the past he has contacted a QHFSS scientist to provide an explanation of the results in a non-scientific manner so he can clearly understand what the result means.

68. Another investigator provided:

(a) He usually has to go chasing the results and he rarely receives a phone call about positive result.

(b) He described the process of result advice as very inefficient and relies on searching the Qprime data base for results, where they are listed under Forensic supplementary.

(c) He stated the DNA unit uploads the results and they are generally forwarded to the Forensic Coordinator as well.

(d) The officer stated the sample will get processed at the QHFSS - a scene link report will go on Qprime - this will then be forwarded as per the usual process to the Crime Manager to the OIC of the relevant unit and then to the investigator.

(e) He said this method of receiving advice regarding DNA is very clunky and a far better system in his view would be a phone call followed up by an email to advise of results. He said in order for this to occur workload considerations of QHFSS/DNA Management Unit staff needs to be taken into consideration.

(f) He provided an example of a murder in his area, [redacted] where a fingerprint was located on a note that was located. The fingerprint of a co-offender was identified on the note and the result was sent through the Qprime process as described above. He stated he only became aware of the identification talking to a SOCO at a later time. He stated this could quite easily occur with DNA identifications as well. The officer stated the communication process of DNA results is an area that needs review to ensure results are provided in a timely manner.

69. It is very apparent from speaking to investigators that ad hoc advice systems exist regarding DNA results. The safety net is Qprime and the Forensic Register which, whilst providing result information, does not necessarily advise the officer of a timely result.

70. Police prosecutors indicated they receive advice of DNA results when they receive a brief of evidence (BOE) which will either contain a statement from a QHFSS person and /or certificate of analysis. Sometimes on receiving a BOE the investigating officer will advise the prosecutor that DNA results are pending if no statement/certificate is attached. One OIC provided the following:

(a) The officer stated in his area they are very invested in their District including early engagement in major crimes with investigators and forensic officers. This involvement includes providing advice to obtaining an understanding of evidence that will most likely be dealt with by staff at his unit in due course. During this process they may become aware of DNA evidence/results. Apart

from this process he receives advice regarding DNA in the form of a BOE which will contain QHFSS statements and or certificates.

71. An officer [redacted]

72. She stated that the DNA Results unit would upload these results on Qprime and the Forensic Register. She stated on occasions she would receive calls from investigating officers querying what specific results meant. She recalled most of the inquiries were surrounding ratios provided on the analyst certificate and a difficulty in interpreting the same.

73. Two OIC SOCO stated generally they will receive an email regarding results for both major criminal matters and volume crime matters where a result is positive. No notification is received for a negative DNA result. They stated phone calls are received by them for DNA positives for major crime. Both officers stated the current system works well in their area. 90% of SOCO's interviewed stated for major crime matters they will generally receive a phone call from the forensic coordinator advising of positive DNA results followed up by an email. They receive no notification of negative DNA results and can access all information regarding DNA outcomes on the Forensic register or Qprime. A forensic manager interviewed stated he does not receive advice regarding DNA results and does not need to in his position. He stated he can check Qprime or the Forensic register if he needs a result.

74. A SOCO interviewed provided the following:

    (a) The officer stated she is often advised of results but not always made aware and she does not know what are the circumstances are as to why or why not they are advised of DNA results.

    (b) She stated in the past she has received email advice about positive hits for DNA samples she has taken. She believes this email is generated by the QHFSS and is also uploaded on the forensic register.

    (c) If there is no match for the DNA example then no email is received, the forensic register is updated to indicate this.

    (d) The officer believes there has to be a better system for result notification, however she has no suggestions as to what that may be. She stated the pure quantity of samples examined by the QHFSS must be taken into consideration when considering a better system for results. E.g., It is not practical to send out 200 emails for 200 samples examined.

75. Thirty-six officers interviewed were questioned regarding their understanding of the result, 'No DNA detected' Out of these twenty-six officers had no understanding that a sample with the result 'No DNA detected' may contain sufficient DNA to obtain a full or partial profile.

Officer type	No understanding	Understanding
Investigator	9	2
Prosecutor	5	1
SOCO	8	2
Scientific Officer	2	4
Forensic Coordinator	1	1
Forensic Manager	1	0

76. Officers stated their understanding of 'No DNA detected' included taking the terminology on face value in that no DNA was able to be located, some officers believed that there was not enough DNA in the sample to detect DNA. The officers that were aware that further DNA testing could be undertaken with regards to such a result were as follows: One officer worked in the DNA Management unit, two investigators, one SOCO and one scientific officer working in specialist units with close liaison to the QHFSS, one prosecutor learnt about this with his involvement in investigation centres working closely with scientific officers and investigators.

77. One OIC of a SOCO unit provided the following:

(a) [redacted] understands, 'No DNA detected' to mean there is No DNA in the sample and that is the end of the process for that sample. [redacted] has had this result numerous times over the years.

(b) This officer could never understand how no DNA was found in blood samples.

(c) The officer did not know this and is very angry as [redacted] tries her best at all crime scenes to get a result for the victim or investigator and prior to this COI finding [redacted] was second guessing [redacted] about [redacted] DNA swabbing ability.

(d) The officer stated she was not aware [redacted] could get further testing done with this type of result. In [redacted] office, they now monitor results more closely and will send matters back for reworking if they feel it is necessary.

78. Several staff could not understand the results of 'No DNA being detected' from a number exhibits sent for DNA analysis to the QHFSS and stated that you just trusted the results as they were the experts.

79. Officers were largely unaware as to what could be done with the DNA samples that returned the above-mentioned result. Eleven investigators and SOCO staff believed there was nothing further that could be done with these results and the hope of obtaining DNA was dead in buried in these cases. Four officers (investigators/SOCOS) stated that they have in the past sent items back for retesting on obtaining these results, whilst

seven officers including two officers from specialist units advised they would send the sample to another laboratory for further testing. A couple of examples below from officers interviewed referring to having matters sent back for retesting to the QHFSS facility or to another laboratory in another jurisdiction.

(a) The officer recalled a serious assault [redacted]. The offender entered the male's residence and seriously assaulted him in the house. Exhibits were sent to the QHFSS for DNA testing and the results came back as no DNA detected. The investigator requested retesting of the samples and again the same result came back. The officer could not believe no DNA was located on the victim's clothes or inside the house. A short time later this complainant died from unrelated matters and no further retesting occurred.

(b) A second officer provided this example in relation to a [redacted] murder [redacted]

(c) Samples for DNA comparison were found on carpet in the deceased's residence. QHFSS could not detect any DNA during their analysis of exhibits and had no other equipment to rework the sample. Sample then sent to either a New Zealand/Victorian laboratory for examination and DNA was lifted.

80. On the whole, officers interviewed advised that if they wished to have DNA samples retested they would need to seek the approval of their forensic coordinator who would enter discussions with the DNA Management unit. This response related to both results of 'No DNA detected' and 'DNA insufficient for further processing.'

81. All officers interviewed were questioned regarding their understanding of the result, 'DNA insufficient for further processing '. Out of these twenty-seven officers had no understanding that a sample with the result 'No DNA detected' may contain sufficient DNA to obtain a full or partial profile.

Officer type	**No understanding**	**Understanding**
Investigator	9	2
Prosecutor	5	1
SOCO	8	2
Scientific Officer	3	3
Forensic Coordinator	1	1
Forensic Manager	1	0

82. Officers stated their understanding of 'DNA insufficient for further processing' included taking the terminology on face value in that there was not enough DNA

present in the sample for analysis. Some officers believed that there was some levels of DNA present but not enough for providing a profile, others believed there was a low threshold of DNA present. Eighteen officers were aware that further DNA testing could be undertaken with regards to such a result were as follows: two investigators, one SOCO and one scientific officer working in specialist units with close liaison to the QHFSS, one prosecutor learnt about this with his involvement in investigation centres working closely with scientific officers and investigators, six other investigators, one SOCO, three scientific officers both forensic coordinators and the one forensic manager.

83. Officers advised of other types of DNA results they recall receiving from the QHFSS laboratory. These include:

(a) DNA detected – straight forward outcome, profile located and person identified.

(b) Mixed profile- more than one profile present.

(c) Two-person mixed profile understanding is what it actually says.

(d) Three-person mixed profile- difficulty in separating profiles to identify a person.

(e) Complex mixed profile – understanding that this profile could not be separated, too many contributors within the profile to obtain a singular profile, multiple samples detected with no singular profile.

(f) DNA unsuitable for meaningful interpretation

(g) DNA profile indicates a presence of possible low-level DNA which is below the forensic DNA analysis reportable threshold – this result was forwarded to an investigator on [redacted] and was in relation to a sexual assault matter.

84. Officers were interviewed regarding training or instruction they had received in relation to DNA including the meaning of the different types of results. All police officers have undertaken basic DNA sample taking as a requirement prior to taking DNA samples from people. SOCOs receive DNA training as part of their initial training to become a SOCO and scientific officers receive training in DBNA in their initial training course. These courses consist of presentations provided by QHFSS staff and includes a visit to the QHFSS facility. No specific training is provided as to the QHFSS processes. Updates are provided in the form of emails or advice to all forensic officers regarding changes to DNA. Refresher courses did touch on aspects of DNA specifically to collection, emerging trends and evolving DNA changes.

85. Almost every officer interviewed, indicated a desire to have some urgent training on interpretation of DNA results particularly since their learnings from the COI interim report. Officers stated even an aide memoir containing what the DNA results mean would be a good start. (See further in recommendations section of this report)

86. The question of the importance of DNA evidence in identifying an offender or conducting an investigation was asked. All interviews stated DNA evidence was very

important and very good evidence. The majority of officers qualified this by stating DNA evidence needed to be supported and/or used in conjunction with other investigative strategies to gain the full benefit of DNA as solid evidence. A number of officers stated DNA is critical in putting a person present at a scene and eliminating people from offences.

87. Prosecutors indicated DNA evidence can mean the difference between a plea or a trial and they find it rare for DNA evidence to be challenged in summary trials or committal hearings. Some described it as excellent evidence.

88. Investigators use DNA evidence for providing direction for investigations e.g., who was present at a scene, where was the DNA located, how did it get there? Investigators involved in historic major criminal investigations rely heavily on DNA evidence to reinvigorate historic matters. The below example highlights the importance of DNA in those investigations.

(a) The officer stated most of the exhibits he deals with are degraded, making detection of DNA profiles somewhat difficult. He stated his team will be advised of a degradation index on exhibits which provides a degradation level of the exhibit.

(b) The officer stated his unit specifically look for quantitative DNA data, or the quantity of DNA in a sample/exhibit. He stated by requesting this level his team can make informed decisions on further testing of an item. He stated different laboratories have different thresholds for DNA. He stated his team are not concerned if the DNA is above or below that threshold and just require quantity numbers, in order for them to make strategic investigative decisions. E.G. If the QHFSS has a higher threshold than the New Zealand (N.Z.) Environmental Science Research (ESR) laboratory, then they will send the sample to N.Z for analysis. He stated they have previously had success in undertaking this strategy.

(c) The officer provided an example of a [redacted] Rape and Murder of [redacted] Some fingerprint evidence was located of the suspect in a van later linked to the offender. A review of exhibits held into this matter identified low copy DNA from a vaginal swab taken off the deceased [redacted]. The quantity of the DNA was quantified resulting in the sample being sent to the NZ ESR lab who conducted an analysis and provided a DNA profile linked to the offender. This evidence along with other forensic evidence led to the arrest of [redacted] who was convicted of the rape and Murder [redacted]. The officer stated these type of quantitative DNA results is a very good tool to send exhibits to other labs who can undertake further testing.

Other Issues – Recommendations

89. Officers were asked to provide any suggestions on what could be done better in collecting biological material for DNA testing or in communicating and training

[redacted]

COMMISSIONER FOR DECLARATIONS
Reg.No [redacted]
DEPT. OF JUSTICE & ATTORNEY-GENERAL

Mark Ainsworth

Witness/ [redacted]

officers and staff about the results of forensic testing. Most officers provided suggestions regarding a range of matters.

Result interpretation and QHFSS capabilities

90. Probably one of the most critical recommendations officers would like to see is a clear aid-memoire or other educational document that is set out in plain English for the interpretation of results from DNA testing that comes out of QHFSS. Many of the officers interviewed stated they were not scientists in did not understand the current methodologies in reporting DNA outcomes particular where scientific figures and ratios are provided. This education could also include what the processes are that are used by QHFSS in eliciting DNA profiles and what other options are available if no quality DNA samples are identified.

91. As indicated by two officers during interview, a specialist unit utilises DNA QUANT data to make strategic decisions about further DNA testing including are their other laboratories available to undertake specific types of testing. Both officers stated the QHFSS staff were very helpful in providing advice regarding further testing and capabilities of laboratories however it appears this testing capability in relation to QUANT data is not widely known in the QPS. From interviews conducted of the two officers, it would appear that QUANT data is obtained from every DNA sample analysed and is entered onto relevant computer systems at the QHFSS. Whilst the data may not be peer checked at that stage, it would provide significant information as to what further testing could be undertaken rather than just producing a result of 'No DNA detected' or 'DNA insufficient for further processing.' This capability needs to be marketed for QPS officers and used to obtain further benefit from DNA testing and the possibility of solving more criminal offences.

92. Consideration of renaming results of DNA to ensure simplicity in understanding and not to discount any further testing possibilities in the mind of investigators or forensic staff. EG. Is there sufficient DNA for an intelligence profile?

93. Several officers would like to see a review of QHFSS hours of operation to provide out of office hours responses to better support the QPS.

94. Case conferencing between investigators, forensic officers and QHFSS staff has occurred ad hoc, depending on the QPS unit and the investigation at hand. Officers have commented on the benefit of this type of consultation with the QHFSS and the value they provide to investigations. Whilst workloads and case files are intense case conferencing on a wider range could not occur but perhaps some consideration could be given to establishing a QHFSS liaison team who could provide a similar service to what is mentioned here. The benefits would be far reaching.

Training

95. A number of officers have identified the need to have an educational tour through the QHFSS facility to receive instruction and to gain an understanding on how the facility operates with respect to DNA. Whilst forensic officers have had visits to the QHFSS in the course of their training, such visits were a look and see without any proper tuition provided regarding processes for DNA extraction. Officer believe this would greatly

enhance their knowledge on what occurs with respect to DNA at the QHFSS but could also generate ideas on how they can better obtain DNA at crime scenes. Several police prosecutors also indicted a desire for something similar in order to provide them with knowledge of process which could assist them in Court matters where a QHFSS person is providing evidence. It could also assist them in understanding statements are little clearer.

96. A scientific officer would like to see enhanced communications between the QHFSS and the QPS. She would like to see joint training days where the QHFSS could gain an understanding of the way the QPS operates and QPS staff could understand the way the QHFSS operate. The officer would like to obtain a better understanding of what QHFSS can and can't do. She would like to see more open dialogue.

97. A number of forensic officers would like to see the reintroduction of refresher training as it were pre-COVID. Officers talked about the great value in those days in educating them and keeping them up to date with trends, emerging patterns and technology.

98. Further education to all QPS officer regarding the importance of taking DNA off persons charged with indictable offences. These samples would be either in the form of an evidentiary sample for the matter being investigated or an intelligence sample if the person did not have a DNA profile on the National system.

Transportation of DNA exhibits to QHFSS

99. A number of remote and regional officers indicated they would like to see a project undertaken around the transportation of exhibits to Brisbane from remote and regional areas of the state to expedite transporting samples to Brisbane. Suggestion of overnight courier service or a model similar to what the Australian Federal Police have which is also courier based. Officers believe this would be a huge benefit to officers in those areas as well as a benefit for complainants whose matters could be expedited.

Other comments during interview

100. The officer stated she would hate to think how many investigations have been discontinued as a result of the issues identified by the COI in the interim report which would have affected further testing being undertaken. She said how many victims have been let down and how many offenders are still walking around the street, who have committed serious and volume crimes. ***(Police Prosecutor)***

101. Frustrations occur where whole blood samples are forwarded and a result comes back from QHFSS of 'No DNA detected/Insufficient DNA for further processing. The officer spoke about a [redacted] Murder at [redacted] where a shirt of the suspect was located hidden away. She took the shirt back to the lab and undertook multiple swab samples of what she believed was blood from the shirt. She undertook a haematology test to the stains which indicated the presence of blood on the shirt. The result took sometime to indicate the presence of blood. The samples were sent to the QHFSS lab and the result came back as No DNA detected. The officer thought this was very unusual that no DNA could be detected. She further stated that in her view she had to rely on the experts at the QHFSS that nothing had been located and that they have undertaken every test they could on the items. ***(Scientific Officer)***

102. Officer stated in his view crime scene examination is generally done very well pertaining to collection, he stated once material goes to QHFSS then the fuzziness starts – you will never know what you are going to get back. ***(Scientific Officer)***

103. The officer would like to see Forensic Officer training including training in DNA to be bench marked against interstate and overseas jurisdictions to ensure forensic officers are operating with the latest knowledge and capabilities. He said this is needed to keep up with the constantly changing science environment. He would like to see it a pre-requisite that the Superintendent at Forensic Services does have a scientific/SOCO background where they can understand scientific processes, challenges and be able to apply a scientific brain to forensic vision and strategies. Someone who can drive forensic capability into the future. He stated in the AFP, WAPOL and SAPOL – Forensic services are run by Civilian Scientists including doctors and allows for a greater knowledge than a manager without a scientific background. ***(SOCO)***

104. Consider a name change to change their current focus e.g., 'Queensland Crime Laboratory.' Have the QHFSS transferred to the QPS. ***(Investigator)***

105. The process undertaken in interviewing these officers hopefully will provide the Commission with information you were seeking. Thankyou for the opportunity to undertake these interviews.

TAKEN AND DECLARED before me at Brisbane in the State of Queensland this [redacted] day of October 2022

Mark Ainsworth Witness [redacted]

Commission of Inquiry into Forensic DNA Testing in Queensland

[redacted] | [redacted] | PO Box 12028, George St Qld 4003 | www.dnainquiry.qld.gov.au

Our ref: COI/DOC/22/

23 September 2022

Mr Mark Ainsworth

Sent: [redacted]

Dear Mark

Re: Commission of Inquiry into Forensic DNA Testing in Queensland

Interviews with staff and officers of the Queensland Police Service (QPS) concerning the methods, systems and procedures for the collection and testing of biological material for forensic DNA testing

1. Thank you for agreeing to assist the Commission of Inquiry into Forensic DNA Testing in Queensland (**the Commission**). The Commission commenced on 13 June 2022 and is required to deliver its final report by 13 December 2022. The Terms of Reference require the Commission to make full and careful inquiry in an open and independent manner with respect to:

   a) whether the methods, systems and processes used by the Queensland Police Service and the Forensic and Scientific Services for forensic Deoxyribonucleic Acid (DNA) collection, testing and analysis are, and have been, reliable, conducted in accordance with best international practice, and result in, and have resulted in, accurate reporting of the presence of DNA in samples submitted for testing and accurate matching of DNA samples; and
   b) whether, if such methods, systems or processes are not, or have not been, reliable, or conducted in accordance with best international practice, or do not result, or have not resulted, in accurate reporting or accurate matching, the reasons for any such failure.

Background

2. The Queensland Police Service (**QPS**) is responsible for the collection of biological material for forensic DNA testing. The one exception to this is the collection of biological material by way of forensic medical examination. Queensland Health staff undertake forensic medical examinations on complainants and accused and obtain samples from those persons. However, QPS are involved in this process by, for example, transporting the samples of biological material once they are taken.

3. Samples of biological material are sent to the DNA laboratory at Queensland Health Forensic and Scientific Services (**FSS**) for DNA testing. The results of that testing are later communicated to QPS via a database called the Forensic Register.

4. QPS do not generally provide physical items to FSS for testing. Rather, QPS officers take samples from a crime scene or physical item, and produce an in-tube exhibit suitable for analysis at FSS without further handling. This 'sub-sampling' process occurs either in-situ at a scene or in QPS laboratories. In some cases, whole physical items are sent to FSS. For example, cigarette butts, condoms and female sanitary items are sent directly to FSS.

5. The QPS Forensic Services Group is involved in the management of the collection of biological material for forensic DNA testing, liaises with FSS, and oversees the receipt of results from FSS.

Commission of Inquiry into Forensic DNA Testing in Queensland

[redacted] | PO Box 12028, George St Qld 4003 | www.dnainquiry.qld.gov.au

6. There are two types of police officers who collect material for forensic DNA testing: Scenes of Crime Officers (**SOCOs**) and Scientific Officers. They are, collectively, referred to as Forensic Officers. For the purposes of your work, we have also referred to Forensic Coordinators as Forensic Officers.

7. Other QPS staff are obviously involved in investigating alleged offences and dealing with the results of forensic DNA testing of biological samples, such as first-responders, investigators and prosecutors.

8. Against this background, the Commission of Inquiry seeks better understanding of the views and experiences of police officers about collecting and submitting biological material for forensic DNA testing, and the level of understanding of police officers about the results of forensic DNA testing.

Your engagement

9. You are engaged to undertake confidential consultation with police officers, especially frontline police officers and their supervisors, with an aim to discover:

    a. whether there are, and if so, the nature and extent of, issues with the collection, transportation and submission of biological material for forensic DNA testing; and
    b. whether there are, and if so, the nature and extent of, issues with the understanding and use of the results of DNA testing.

10. We **enclose** a list of questions to assist you with a semi-structured interview process (**Attachment 1**), but you are able to ask such further questions as you consider appropriate.

11. We understand that you will, at first instance, use your contacts within the Queensland Police Service to identify a number of persons you will approach to engage in that confidential consultation. If any interviewees suggest other people who may be willing to engage with you, or if other police officers approach you, you are able to engage with such people. Importantly, we would like you to speak to:

    a. forensic officers (scenes of crime officers, scientific officers, forensic coordinators);
    b. staff and officers who are not forensic officers but who are involved in the investigation of, or response to, instances of crime, including at least some who have experience in investigations in which a forensic medical examination occurs; and
    c. police prosecutors (who will, in effect, only be asked questions 1 to 4 and 19 to 25 in Attachment 1).

12. While the interviews are to be semi-structured, we request that you ensure each person is asked questions 19 to 24 and their response for each question is noted.

13. We also **enclose** some information about the confidential nature of your interviews (**Attachment 2**) that you can explain to each interviewee. In short, although we will ask you to report the position, rank, number of years of service and district of each interview, we will not receive the name or age of the interviewee, the station they work at, or any other details about the interviewee that might cause them to be identified. If an interviewee is concerned that their position, rank, years of service and district are likely, in combination, to identify them, this should be noted and the Commission will make best efforts not to disclose all that information to other parties in a way that might identify the interviewee.

14. The Commission would prefer that each interview be audio-recorded for accountability and record-keeping purposes. If an interviewee requests that the interview not be recorded, you are able to conduct that interview without a recording, but it is important that you keep detailed notes in that case.

Commission of Inquiry into Forensic DNA Testing in Queensland

[redacted] | [redacted] | PO Box 12028, George St Qld 4003 | www.dnainquiry.qld.gov.au

15. Although the default position is that each interview is to be conducted on a confidential basis, the Commission would like you to enquire of each interviewee whether they would be willing to have their response made public, or to give evidence at a public hearing.

16. We ask that, when you meet each interviewee, you do so at a location other than the interviewee's workplace, and not while they are wearing their uniform.

17. The Commission would be grateful to receive a brief update from you, each day or couple of days, which identifies the rank, position and geographical location of any interviewees you have spoken to since your last report, as well as a very brief description of the kinds of information you gathered from the interview.

18. The Commission anticipates that you will consult, as widely as possible, for a period of approximately two and a half weeks commencing Monday 26 September 2022. This consultation period may be extended by agreement with the Commission.

19. In order to consult as widely as possible, the Commission understands that you might travel to different locations across Queensland. Reasonable travel and accommodation costs will be reimbursed by the Commission in accordance with the terms of your contract of engagement.

20. The QPS and Queensland Police Union of Employees are being informed that you have been engaged to undertake this work.

Timing

21. Following that period of consultation, please provide a written report summarising your findings. The Commission would like to receive the report as soon as possible after the end of your consultation period, and, if possible, by **13 October 2022**. Upon receipt of that report, the Commission may wish to call you to give evidence about your findings at a public hearing, potentially between **19 and 21 October 2022**.

Contact

22. Thank you in advance for your assistance. If you have any questions about your engagement, please do not hesitate to contact counsel assisting Joshua Jones at [redacted] or [redacted]

23. Your primary points of contact at the Commission will be Joshua Jones and Carl Tessmann; the latter can be contacted at [redacted] or [redacted]

Yours sincerely,

[redacted]

Walter Sofronoff KC
Commissioner
Commission of Inquiry into Forensic DNA Testing in Queensland

Encl.

Attachment 1 – Questions for Police Officers

Personal details

Questions for all persons

1. Position
2. Rank
3. Years of service
4. District/region

Collection

Questions for all persons except police prosecutors

5. What is your involvement with collecting biological material for forensic DNA testing? (For example, a scenes of crime officer (SOCO) may regularly take DNA samples from the site of property crime or violent crime; a uniformed officer may identify the need to contact a SOCO to attend a scene of crime, and take DNA samples from an accused).

Questions for persons who are not a forensic officer[1] or a police prosecutor

6. If you are involved in arresting or charging accused persons, how often, when you arrest or charge a person with an indictable offence, do you take a DNA sample from that person?

7. Are you aware of any issues or problems related to the collection, transportation or submission of biological material? This may include, for example, issues with the availability of forensic officers to attend a crime scene, delays in transporting biological material, contamination issues, or security issues at property points. Provide examples if possible.

Questions only for forensic officers

8. Are you aware of any issues or problems related to the collection of biological material? For example, being short-staffed and unable to attend all crime scenes, equipment is deficient or insufficient, there are contamination issues, or other procedures are generally not followed. Provide examples if possible.

9. What is the key policy (or policies) related to collecting and dealing with biological material?

10. What refresher training do you receive, and how often does it occur? What ongoing proficiency testing do you undertake?

11. Do you feel that your initial training and refreshing training is adequate? If not, why not? What training would you like to receive, if any?

[1] For the purposes of these questions, 'forensic officers' are Scenes of Crime Officers, Scientific Officers and Forensic Coordinators.

Forensic medical examinations

Questions for all persons except police prosecutors

12. Do you have (currently or in the past) any involvement with complainants and/or accused who undergo forensic medical examinations, or any other indirect involvement with forensic medical examinations, including involvement with the equipment used or transportation of the samples produced?

Questions only for persons who answer 'yes' to question 12

13. Who conducts forensic medical examinations in your area? Does a complainant or accused get to choose the gender of the medical examiner? Have you experienced any issues with the availability or willingness of medical practitioners to conduct forensic medical examinations, either on a complainant or an accused?

14. Who is responsible for providing the practitioner with a sexual assault investigation kit (**SAIK**)? Where are SAIKs stored, and where are they obtained from, if you know? Have you ever had issues with the availability of SAIKs?

15. Where do complainants wait for a medical practitioner to become available to conduct a SAIK, and how often do they typically wait?

16. How are SAIKs transported to the Queensland Health DNA Laboratory? How long does that typically take, if you know? Have you had instances where it has taken more than two weeks for the SAIK to reach the DNA laboratory? If yes, provide details.

17. In your experience, is a reference sample taken by the medical practitioner while administering a SAIK or is it later taken by a police officer? If later taken by a police officer, have complainants every complained about having to undergo a further DNA test?

18. Have you observed any issues with respect to forensic medical examinations, or SAIKs (such as the turn around time for results of testing, or restrictions on the ability to submit other samples for testing during this time), or do you have any suggested improvements in this area?

Results of DNA testing

All persons must be asked questions 19 to 24

19. Are you ever advised of the results of DNA testing?

    a. If yes, how are you notified of those results? (Identify if the type of notification varies between the type of sample taken, or the type of result).
    b. If no, would you like to be made aware of the results of the DNA testing of biological material that you collect or are involved with?

20. In relation to the result '*No DNA detected*' (or similar)

    a. What is your understanding of this result? If you have not seen this result-type before, confirm same.
    b. Prior to the public release of the Commission's interim report, did you understand that there may be sufficient DNA in a sample reported as "No DNA detected" to get a full or partial profile?
    c. What options did you consider were available for further testing if such a result was received, if any.
    d. [*If the person advises they understood further testing was available:*] Who did you understand could request further testing?

21. In relation to the result '*DNA insufficient for further processing*' (or similar)

    a. What is your understanding of this result? If you have not seen this result-type before, confirm same.
    b. Prior to the public release of the Commission's interim report, did you understand that there may be sufficient DNA in a sample reported as "DNA insufficient for further processing" to get a full or partial profile?
    c. What options did you consider were available for further testing if such a result was received, if any.
    d. [*If the person advises they understood further testing was available:*] Who did you understand could request further testing?

22. What other results do you recall receiving? What is your understanding of those results?

23. Have you ever received any training or instruction in DNA evidence, including the meaning of the different result types?

24. Do you find DNA evidence is often or sometimes important in identifying an offender, deciding how to investigate a case or building a case against an accused? If yes, provide examples. Provide details if other types of evidence are typically more important than DNA evidence.

Other issues

Questions for all persons

25. Do you have any suggestions about what could be done better in collecting biological material for DNA testing, or in communicating and training officers and staff about the results of forensic DNA testing?

Attachment 2 – Confidentiality information for police officers

The Commission of Inquiry into Forensic DNA Testing in Queensland is considering, among other things, whether the methods, systems and processes for the collection of biological material for DNA testing is reliable and conducted in accordance with best international practice. As a result, the Commission is trying to understand:

a. the nature and extent of any issues with the collection, transportation and submission of biological material for forensic DNA testing; and
b. the nature and extent of officers' understanding and use of the results of forensic DNA testing.

As a result, it is important the Commission hears directly from police officers.

Your responses will be anonymous.

I will ask you to provide some information about you and the district where you work as a police officer, however, you will not be able to be identified from these responses.

You will not be asked to provide your name, date of birth, age or address.

I will not ask you to sign any consent to participate in this interview for anonymity purposes.

When I report on my findings from this consultation process to the Commission, I will inform the Commission of your responses, but not in a way that can identify you. Although your responses will be able to be taken into account by the Commission in undertaking its work, no individual survey participant will be identified or identifiable in the Commission's report, and your responses will be treated with respect and confidentiality.

SUPPLEMENTARY REPORT

Report into interviews conducted with police officers and civilian officers of the Queensland Police Service concerning the methods, systems and procedures for the collection and testing of biological material for forensic DNA testing, pertaining to the Commission of Inquiry into Forensic DNA testing in Queensland.

1. As previously stated during the course of my role I conducted interviews of eight SOCO's from various locations across the State. The question of contamination of DNA during the collection process was asked of each officer (Question 8). In addition to paragraphs 34 to 36 of my initial report (pertaining to officers' responses to contamination), I would like to add the following.

2. Three out of the eight SOCO's interviewed indicated difficulty at crime scenes when using trace DNA tape lifting equipment. The officers stated that the tape is very difficult to work with in that the tape tends to roll back on itself when officers are attempting to insert it into the exhibit tube. One officer described the tape lift equipment as similar to a clear sticky tape substance which they dab down onto stains at a crime scene to try and lift DNA. The officer stated the tape is mostly used on porous surfaces including clothing. Officers were concerned regarding the possibility of contamination of a sample whilst attempting to place the tape lift into the exhibit tube. This contamination can occur by the SOCO themselves during this process.

3. One officer would like to see if there is a better methodology in existence for lifting trace DNA other than the current tape lift, in order to prevent possible contamination of the exhibit.

TAKEN AND DECLARED before me at Brisbane in the State of Queensland this 20th day of October 2022

[redacted] ....[redacted]

Mark Ainsworth Witness [redacted]

COMMISSIONER FOR DECLARATIONS Reg.No.: [redacted] OF JUSTICE & ATTORNEY-GENERAL
